Publishers.

SAN FRANCISCO, SATURDAY, JULY 3, 1886.

VOLUME LIII.  
Number 1.

## Government Engineering Work.

Government engineering work on this coast is just now pretty much at a standstill for want of the necessary appropriations. There is nothing whatever being done with the harbor fortifications, nor has anything been done for several years, though our present defenses are acknowledged to be inadequate and antiquated. At Mare Island there is no shipbuilding being done, and the drydock is not completed. On Oakland harbor the dredging has been stopped, there being no more available money. At the San Pedro harbor improvement, work is dragging slowly on, also hampered by insufficient appropriations. The lighthouse department also finds itself delayed on important work for similar reasons. All the parties of the Coast and Geodetic Survey have been called in from field work, because no appropriation has yet been made, and even the expected amount is far short of what is needed, so that many assistants will be dropped.

This is a very unsatisfactory state of affairs, indeed. In the matter of rivers and harbors the Pacific Coast is badly off, there being very few good ones; but in improving what few there are the Government engineers have had very difficult work in getting the necessary money. Work that should be completed in three years takes 10 or 15, owing to delays in appropriations. This makes the cost excessive and discourages those in charge.

The present system of appropriations for public works is fatal to their efficient conduct, and is productive of disaster and extravagance. By this system engineering considerations are entirely disregarded.

Appropriations are made by the contending influence of private interests, and in amounts which have no relation to the importance or cost of proposed works, but result simply from mutual concessions among these interests, to the end that the total of an appropriation bill may not become insupportable.

Appropriations for new work are made in spite of adverse recommendation from the Chief of Engineers and his subordinates; and works begun are in subsequent years left wholly unprovided for or starved by insufficient grants of money.

It results that exact preliminary estimates are impossible, and that, with one exception, there has not been an important river and harbor work undertaken in this country during the last 20 years which has not been made extravagant in cost or jeopardized in success by the financial uncertainties of the present irrational and improper system. The one exception is the case of the Eads jetties, at the mouth of the Mississippi, and for these Congress made a radical departure from its usual course, and in one act made provision for the entire work.

There seems to be no ground of hope for remedy of these regulative abuses until the evils of the present system have become so grave and plain to the public mind as to force the abandonment of the present indiscriminate efforts at river and harbor improvements of the General Government. That the present system is lamentably imperfect is readily admitted by the officers at present charged with the execution of the improvements. They could do much less costly and more satisfactory work were money available at the times when it is necessary, and so that work could be continuously carried on.

## The Improved Hartsfeld Furnace.

The accompanying engraving represents the Hartsfeld improved desulphurizing, roasting and smelting furnace. It is especially adapted for the economical treatment of low-grade rebellious ores containing much sulphur, arsenic, etc., which generally require a previous roasting. The improved furnace has a wet metal-dust con-

saves 10 per cent of the original weight of the ore, and there is no drawback to any portion of the machinery." The result of the test run banishes all doubt as to the success of the enterprise, and we heartily congratulate Mr. Brile and the company on their success.

These furnaces are manufactured in four sizes, by Lane & Bodley, of Cincinnati, Ohio; W. T. Garratt & Co., San Francisco; Imray &

IMPROVED HARTSFELD DESULPHURIZING SMELTING FURNACE.

denser attached to it. The engraving shows the construction of the furnace quite clearly.

The following paragraph, from the *Coeur d'Alene Record*, gives the result of work with one of these furnaces. Through the courtesy of Alfred Brile, superintendent of the Kentucky Mining and Smelting Company, we have the following report of the test made by his company at Milo, Idaho: "We started at 8 A. M. May 26th, and tapped the first slag 30 minutes later. The ore run came from different mines. The furnace was started without lead in the lead well, and after a run of four hours, seven bars of bullion, weighing 700 pounds, were drawn. The average amount of ore run while test was being made was 2500 pounds per hour, equal to 30 tons per day in a No. 20 furnace. The slag run like water. After smelting 60 tons of ore, the bottom was dropped, with the furnace thoroughly cleaned. The condenser

Co., London, England; McIlvain & Spiegel, Cincinnati, and the Hartsfeld Portable Smelting Furnace and Mining Co., Newport, Ky. The latter-named company will forward catalogue, etc., on application.

**NEW SILVER VAULT.**—The House evidently has no thought of the suspension of silver coinage within the next four years, as an appropriation of about \$112,000 for making additional storage room in the Philadelphia Mint building has been voted without opposition. The additional space will be sufficient to store \$60,000,000.

**THE Young America quartz mine** of Sierra City has become a solid dividend payer, the aggregate of the seven monthly dividends paid being \$85,000. The last dividend, recently paid, amounted to \$15,000.

## To Work by the Elevator Process.

We note in the *North San Juan Times*, of Nevada county, that a hydraulic gravel elevator is soon to be placed in operation on the property of the well-known North Bloomfield Gravel Mining Company, at North Bloomfield, Nevada county, this State. We have interviewed the manager of the "Joshua Hendy Machine Works" of Nos. 39 to 51 Fremont street, this city, and learn from him that this report is true, and that they have now in process of construction at their works a No. 3, 20-inch gravel elevator, which will be in operation on that property in about two weeks.

L. L. Robinson, Esq., the president of the famous North Bloomfield Company, has thoroughly investigated the principles governing the operation of these elevators, has practically experimented with one of crude form, has had reports by experienced hydraulic mining engineers furnished him of the actual work done by these mining devices at Mammoth Bar, Placer county, and on the ground of the Miocene Mining Company, in Butte county, and upon the strength of the information which he has gathered, the knowledge he has acquired and the representations made to him of their practical utility, has entered into an arrangement with the above-named "Joshua Hendy Machine Works" whereby those works agree to place an elevator of the largest size yet constructed, and of an improved form, upon the ground of this company. Being supplied with a sufficient volume of water, acting under a vertical pressure of 425 feet, they propose to raise earth, sand, gravel, water, etc., through this elevator into an outer line of sluice-boxes, at a height of 80 feet above the lower or entrance section of the pipe. An attempt will also be made, under the same conditions of volume and pressure of water, to raise earth, sand, gravel, etc., to an elevation of 100 feet, and it is believed that this can and will be accomplished.

We shall watch with great interest the course of these operations, and shall present the result of our observations to our readers, and full information of the progress and accomplishments of this interesting and important work.

In the present condition of the hydraulic mining industry of our State, a solution of the vexatious problems involved in the "debris question" is one of vast importance. If, as is expected by this system of mining, all debris can be impounded within the limits of the ground that has already been mined and exhausted, then many of the valuable properties which now lie virtually abandoned, by reason of adverse legal decisions and legislation, may again be successfully worked, and a golden stream will pour into the channels of commerce, and the honest miner will then be made happy, and the useful granger cease his complaints. These hydraulic gravel elevators are in successful use in numerous mines in this State and Colorado. The North Bloomfield is the most extensive hydraulic mine in the world, and the adoption of the "elevator system" there will doubtless lead to a more general knowledge of its advantages under certain conditions.

**THE Mechanics' Institute Fair** will open on August 24th. It has been decided to appoint 16 jurors to pass upon all the classes except agriculture, county exhibits and fruits and cereals. They are to be assisted by a competent secretary.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

## The Great Central Plateau of the Southwest.

Its Natural Wealth and Resources.

[Written for the Press by J. G. LEMMON.]

If the reader will examine a late map of the southwestern Territories he will, at a glance, notice a long line of railway running nearly straight across the northern part of Arizona, and extending eastward nearly to the center of New Mexico.

On close inspection this line will be seen to follow along the 35th parallel of north latitude, varying only a few miles north and south of this parallel at any point.

Also it will be seen to span the whole distance between the two great rivers that flow southwardly out of the Rocky Mountains—the Colorado and Rio Grande—separated on this parallel by just eight degrees of longitude, equaling at this latitude about 50 miles each, making an air-line distance of about 400 miles.

The Railway Guide-book will inform you that the 35th parallel road, despite the sinuosities a railway must make to find the easiest grades, spans this distance by a course of only 560 miles.

The guide-book will also show the newly established town of Needles, on the Colorado river, as the western terminus of this road; also that this town is connected with the farther West by a continuance of the line to Mohave, on the Southern Pacific Railroad from San Francisco to Los Angeles and the southwest.

Also the guide-book will inform you that the larger, more important town of Albuquerque, on the Rio Grande, enjoys the double advantage of being both the eastern terminus of the road described and also of being a central depot of the Atchison, Topeka & Santa Fe road, coming from the northeast on its way down to El Paso and the southwest.

## The Great Central Plateau.

This much the map and guide-book will show, but the most prominent feature of the country is not readily conveyed to the eye by a flat surface like a map. This feature is a high, long and broad plateau occupying this interspace, and over which the railway climbs and descends.

The great plateau is somewhat quadrangular and oblong in shape, the longer diameter being east and west. Its high center remains convex, like a broad sugar loaf, but its sides all around have been abraded and carried away by ages of weathering, the debris conveyed to Southern Arizona and New Mexico and spread over their valleys by the affluents of three great rivers, which almost entirely inclose the plateau.

The Colorado and Rio Grande form the nearly straight west and east boundaries of the plateau respectively, while the grand canyon of the Colorado river, turning abruptly eastward near the northwest corner of Arizona, together with its principal and also deeply-canyonized branch, the San Juan river, bound the irregular northern side. Similarly, but not so deeply, the Gila river, with its affluents, drain the still more irregular southern side.

This plateau is so large and diversified that characteristic names have been applied to the several mesas or benches composing it.

## Mesas and Mountains.

Hualapais and Chino valleys, with the Aubrey and Prescott mesas and a large diversified plain south of them, comprise the western end of the plateau; the San Francisco mesa comprises the great forest on the Arizona divide; east of it, stretching to the continental divide, is the large Colorado mesa with the Mogui and Navajo reservations north and the White mountain reservation south of it; lastly, in Northwestern New Mexico, is the broad continental divide with the Zuni and Mogollon mesa south of that.

The most conspicuous mountain groups rising out of the mesas along the north side of the plateau are, first on the west, the several Hualapais ranges, the Prescott ranges, the Bill Williams group, the San Francisco group with its mountains Agassiz and Humphry over 13,000 feet high—the highest peaks in Arizona—the Sierra Madre on Zuni range on the continental divide, and the San Meteo group, with its Mount Taylor, over 13,000 feet altitude, the loftiest peak in New Mexico.

Another line of groups are the Granite, Superstition, Manizeta, Pinal, White—with its Mounts Thomas and Ord, over 11,000 feet altitude, and the rugged Mogollon mountains remain prominent on the southern slope of the plateau.

## Principal Rivers.

Chief of the rivers originating on this plateau is the Little Colorado, a considerable stream some 250 miles long, which, with its many branches, alternately drains and irrigates the broad central portion between the two divides, cutting for itself at last a deep gorge on the north side through which it debouches into the main Colorado just at the head of the Grand canyon.

Similarly, but on a smaller scale, the Salt river disports itself on the south-central part of the plateau and then empties into the Gila above the Big Bend. Bill Williams and Rio Puerco

are minor streams on the western and eastern ends respectively, each contributing largely to the wealth of the plateau.

## Towns and Settlements.

Several important towns, including the capital, Prescott, are situated on this plateau. The capital and Mineral Park are on the western slope, the former about 50 miles south of the A. & P. R. R., the latter 20 miles north of it.

Similarly situated, on the eastern slope, are St. Johns and the other Mormon settlements, all on the Little Colorado and its branches.

A dozen new and promising towns have sprung up along the line of the railway. Beginning at the west, Kingman is the depot for Mineral Park, Peach Spring for tourists, to the Grand canyon of the Colorado, Ash Fork for Prescott. Williams is an important mountain town. Flagstaff is at a higher elevation than any other town on the plateau, 7000 feet in the great pine forest near the base of the lofty Mt. Agassiz. Winslow is the depot for some of the Mormon settlements, Holbrook for St. Johns and other Mormon settlements, together with several other important and growing towns; Wingate, for the port of that name, and the ancient Indian town of Zuni, while McCarty's station is the radiating point to several Indian pueblos and Mexican towns near the Rio Grande.

A half-dozen military posts have long been established on the plateau, including Fort Whipple near Prescott, the headquarters of the department commander.

## Atlantic &amp; Pacific Railway.

The long, nearly straight thoroughfare described as traversing this plateau from end to end, is the lately-constructed and superbly-equipped middle division of the Atlantic & Pacific or Thirty-fifth Parallel railway, in praise of which, and the scenery it reveals, together with the natural wealth and resources it unfolds, much has been written of late, and deservedly, too, for it is one of the most interesting and important routes thus far projected on this continent.

This results from its traversing a region studded with more extreme, diverse, beautiful, grand, curious, wonderful, important and valuable objects than can be combined by a road of like extent through any other part of the globe. And this region is not alone to be penetrated by this road, for already two important feeders have been surveyed, one across the western end of the plateau reaching down southward to Prescott, and thence to Phoenix, in the rich valley of the Salt river, continuing on across the Gila river to connect with the grand trunk of the Southern Pacific at Maricopa; the other traversing the middle portion from Flagstaff through the length of the great forest to Globe City, and making another connection with the Southern Pacific at Wilcox.

Each of the foregoing adjectives applied to the region traversed by the A. & P. R. R. could be substantiated by pages of detailed description, but the requirements of journalism demand of the note-taker brevity and point.

## Extremes and Diversities.

Exceeding diversity results from the great difference of altitude of the several parts of this plateau. Taken as a whole the plateau is inclined on its bed so that its western end is depressed to nearly sea level at the Colorado river, while its center rises to over 7000 feet at two points—the Arizona summit and the Continental divide—descending to about 5000 feet at the eastern end resting on the Rio Grande; and all this extreme of elevation is under the semi-tropic parallel of 35 degrees, thus insuring the widest diversity of flora and fauna.

The low Colorado valley, the hottest region within the limits of the United States, with its burning desert sands yielding their peculiar thorny flora of cacti, yucca and agave, under which lurk noxious reptiles and above which swarm stinging insects, contrasts very strongly with the elevated and delightfully cool great central crown with its gently undulating valleys and hills, all clothed with a wealth of pine, oak and juniper forests and carpeted with beautiful flowers and nutritious grasses, upon which feed graceful quadrupeds and above which float lovely song-birds; while rising here and there from out the evergreen forests like icebergs on the billowy sea, several isolated groups of bald peaks ascend from 12,000 to 13,000 feet in height, so lofty, indeed, as to retain perpetual snow in their northern canyons, once the track of grinding glaciers.

## Beautiful and Grand Scenery.

Most beautiful are the flowers, shrubs and trees; the canyons, water-courses and valleys; the groves, meadows and vistas revealed by this road; while the extensive forests, noble mountains and bristling peaks attain the magnitude of grandeur. Awe-inspiring sublimity reaches its climax on this continent in the Grand canyon of the Colorado, near the great southern bend of which, at Peach Spring, this railroad fortunately passes. This canyon is over 200 miles long. Its walls are from 4000 to 6000 feet high, and irregularly cleft from top to bottom by side canyons that leave segments of rock between them, fashioned into magnificent pyramidal, castellated mountains, zoned about with horizontal, parti-colored strata, from river-washed base to cloud-wreathed summit.

## Curious and Wonderful Objects.

Very wonderful are the roomy, white-furnished limestone caves recently discovered near

Peach Spring and Ash Fork, while still larger and more wonderful ones have been found in the White mountains; the latter abounding in ancient pottery, burial urns, weapons and utensils of curious design and unknown origin.

On the plateau near Chiquita, Colorado, the former traveler over the plains suddenly found himself, without warning, on the very verge of the famous Canyon Diablo, a deep rift in the earth's surface 30 miles long, 222 deep and only 540 feet across, channeled by a deep stream ages ago. This frightful gorge is now spanned by a much-admired iron bridge, over which all trains pass slowly to allow passengers time to gaze into its awful depths.

Most wonderful and puzzling is the petrified forest near Holbrook, trees of which have been measured that were three to four feet in diameter. The cracks and cavities of these trees are filled with masses of lovely polygonal crystals of many hues, being the residue of the silica which was taken up in solution by these trees during a series of dry seasons, ages ago, and thus deposited, after which the celluloid tissue of the heart-wood was filled to repletion, and the trees became solid stone. A company has been incorporated in San Francisco to obtain and manufacture tons of these petrifications into jewelry and all sorts of fancy as well as useful articles.

## Interesting Aborigines.

Most interesting to tourists and important to naturalists are the persons, habits, occupations, surroundings and traditions of the aborigines, many tribes of which are located on this plateau.

These Indian tribes present all degrees of physical condition and mental culture, from the squalid, beggarly Hualapais, huddled under the junipers of the western slope, who hesitate at nothing degrading and criminal, to the high-spirited, stock-raising Navaho, roaming over the upper mesas; or the still more advanced and Christianized, agricultural Pueblo Indians, dwelling in excellent stone houses of extremely ancient origin on the eastern slope.

The Indian topic is so very interesting that the temptation is strong to enlarge upon it at this time, but such amplification may be indulged, perhaps, in a subsequent paper.

## Salubrity of the Climate.

The high elevation of the plateau, the mildness of the summer's heat and the winter's cold, the absence of hot winds and piercing blasts, the presence of balsam-producing trees in the forests, the purity of the mountain springs and streams, all combine to make the sanitary conditions exceedingly good.

Already the region has become a resort for invalids seeking health, and persons afflicted with chills and fever elsewhere lose all symptoms of the malady soon after arriving on the plateau. No malarial districts, even of small extent, have been detected on it, and their presence is believed to be impossible.

Rheumatic and nervous disorders are infrequent, while pulmonary and bilious complaints never originate on the plateau.

The few physicians that strive to make a living here have very large circuits and each has some other business—the sale of drugs, the raising of stock, etc.—connected with his profession. They declare that their practice consists almost entirely of surgery and obstetrics.

## Great Wealth of the Plateau.

Finally, the economic values of the objects developed and brought into commercial relations with other parts of the Union by this new railway are simply past computation.

First may be mentioned the saving of time—and time is often of more worth than money to the tradesman or traveler—insured by a direct thoroughfare between the East and West which is absolutely unmenaced by snow-blockades in winter or sandstorms and washouts in summer. The real wealth of this Mesopotamia region is but fairly discoverable now, not yet fully developed. It consists mainly of several rich mines comprising nearly all the precious metals, already putting out carloads of bullion and hundreds of prospects more or less developed in all the mountain ranges of the plateau; of vast coal fields supposed to be the largest in the world, underlying the north-central part of the plateau, extending also into Utah, while southward they are crossed by the railway at Gallup, where five thick strata crop out and are extensively worked; of wide forests of pine, cedar, fir, juniper, oak, ash and other timber trees, among which already many saw-mills and factories are established, using improved machinery and employing hundreds of workmen; lastly, and perhaps chiefly, of stock-raising, beef-producing and wool-growing facilities, prosecuted for hundreds of years by the pastoral Indians and now being seized upon and improved by the dominant white races.

## Unexcelled Grazing Lands.

It is believed that no other country in the world is possessed of such wealth of grazing lands as are found on this plateau. Nutritious grasses, thick, and often two and three feet high, abound in the valleys and amid the trees of the great forest, while shorter and more tufted, but just as rich and abundant, clothe all the other portions of the plateau at lower levels, especially in the broad juniper belt, which entirely surrounds the great forest, and which, in fact, composes the greater part of the plateau.

## Seeming Drawbacks.

To the traveler on the railway or the thoughtless observer anywhere, there seem to be two

serious drawbacks to the superior excellence of this plateau as a grazing country. One is the presence of *Malpais* rock over large portions; the other is the scarcity of water over most of it. Both these facts, however, are found to be really great advantages to stock-raising and fattening.

*Malpais*—"bad land" or "bad country" in Spanish—is a black or various colored lava, hard and porous, which is found shattered at the surface, and strewn over large areas of the plateau, especially at the center, where, perhaps, it originated in the San Francisco and neighboring mountains. Its presence prevents animals from stampeding or running great distances, but does not hinder slower progress anywhere, especially in the numerous valleys, where it is partially or wholly covered with alluvium.

Large stock-raisers of many years' experience declare that they would not have the *malpais* removed from their ranges for any consideration, for it keeps their animals quietly at home, thus greatly favoring fattening and increase.

The wild, long-bodied and long-legged animals from Texas and similar smooth plains have been made so by the habit of running and stampeding to which they have been subjected all their lives. Brought upon this plateau, their offspring in a few generations become tame and gentle, with short legs, thick bodies and deep chests, while every circumstance favors milk-yielding and fattening processes.

## The Water Supply.

While it is well known that springs and so-called "tanks" or sink-holes in stream-beds are everywhere dispersed at convenient intervals—and of these more can be readily developed by intelligent effort in many places—yet there is at present a comparative scarcity of water.

This scarcity serves a similar purpose as the *malpais*, in keeping animals quietly at home, and hence it greatly diminishes, or entirely obviates, the expenses of herding. An instance was cited to the writer where a stock-raiser in the region easily cares for over 1000 head without assistance.

Stockmen find that one herder can care for five times as many animals in such regions as where water is so abundantly and equally distributed, for the herder has only to visit the watering places for his stock instead of searching over the whole country.

Still, there are certain districts lying idle because they are entirely destitute of water except in winter and midsummer. In these localities enterprising natives are boring artesian wells, and the day is not far distant when the construction of reservoirs in favorable gulches, or the converting of certain canyons and valleys into lakes, will be found a profitable investment of capital.

## The Mild Winters.

As a climax to this matchless array of stock-raising and fattening facilities it only remains to mention the highly favoring, mild, open winters.

All the domestic animals, including sheep, require no special care or provision in winter as regards either food or shelter. At the approach of the first storms the animals not already favorably located roam off into the juniper belt, to feed upon the hitherto untouched grasses, coming back or being driven back in the spring, fat and ready for market, with seldom the loss of over one per cent.

Let Eastern farmers who have to build barns and then toll three or four months of each year to fill them with hay, then toll another three or four months to feed the hay out to stock, in a freezing atmosphere, let them learn of this glorious outlook on the great central plateau of the Southwest, where millions upon millions of acres of these grazing lands lie all unoccupied and inviting Anglo-saxon enterprise.

Flagstaff, Arizona, June 2, 1886.

## Comparative Value of Quartz Mills.

EDITORS PRESS:—An article appeared in your issue of June 12th, written by some party in this place, bearing the signature of "The Old Man of the Mountains," and the attempt is made to reply to a late communication of my own over my name, entitled "Comparative Trials of Quartz Mills."

I propose to be brief in what I here say and not to deal in loose generalities that have neither weight, point nor brilliancy. This is an easy thing to do, but to give the true figures and facts as I did, and which he did not, is quite another thing. He makes ducks and drakes of the whole matter, misses the true point and is evidently of the old and probably of the foreign and unprogressive school.

He is certainly unaware of the advance made in the many different modes of crushing quartz in America, and especially in California, and is politic enough to shield himself under a non de plume, a circumstance indicative of timidity and consciousness of weakness. He has one advantage of fighting behind a fence. This is safe but not brave, and is not the usual manner of men knowing what they are writing about and having the courage of their convictions. Let him give, over his proper name, his experience in the matters whereof he writes, stating descriptions of different mills he has used, if any, and names of places and persons and the results obtained. I am prepared to give mine dating back to 1865. Otherwise, his bare assertions about primitive mills, etc., are the

veriest stuff and will carry no weight among men of practical experience.

I recognize as well as "Old Man" does the true value of stamp mills, and know thoroughly well the improvements made in them in late days, and have suggested several myself, of which "Old Man" never heard, and have used both gold and silver stamp mills of the largest size. He must be blind to the spirit of this progressive age and utterly inexperienced with other forms of mills, and therefore incompetent to make statements as to their comparative values. Does he pretend to say that stamp mills have exhausted invention? If so, the statement is simply reckless and the offspring of prejudice or ignorance, or both, for prejudice always comes from ignorance. The facts tell directly and exactly the reverse of his position, for mills of various kinds, other than stamps, like the Huntington and Tustin & Kendall, and now the Frisbee & Lucop mill in operation at the Pacific Iron Works, are running successfully in many places on the Pacific Coast.

"Old Man," as he styles himself—rather appropriately, I fancy; old and therefore prejudiced in favor of old things—may be ignorant of the fact, but it is nevertheless a fact known and admitted by men of intelligence and information, who keep abreast of the times.

Allow me to quote poetry for a moment. It is applicable to the point:

A little knowledge is a dangerous thing;  
Drink deep, or touch not the Pierian spring.

He alludes to me personally by name. Let him state his. He may be a fairly good assayer, or may run a little thumping five-stamp mill. When I know who he is, I may not say as much for him as he has said for me. *Nous verrons.*

It happens that a small object placed near the eye will conceal the largest at a distance. I judge his mental vision has been thus affected.

I know by actual practical use the principle and the comparative value of the different kinds of quartz mills, old and new, operating on this coast, and am informed by competent and experienced men as to those in the East; and when I made the comparison as to the value of different forms of mills, I felt confidence in stating my belief, based on facts and figures derived from such personal use and close and prolonged observation, and now feel that your readers will not be misled by general and loose statements, for they hold men strictly to proof, and the reasons for the faith that is in them as to all matters of scientific interest and practical value; and I know of no paper that has been so instrumental in educating men in this inductive system as the MINING AND SCIENTIFIC PRESS.

LOUIS BLANDING.

Sonora, Tuolumne Co.

### Gold Yield of British Columbia.

The following summary of mining operations and statement of the gold product of British Columbia is taken from the reports of the minister of mines for the province, for the year 1885. Every indication now is that the yield for the current year will be a much larger one than that of last season. There have been new finds in some districts, and at Cassiar some of the tunnels which have been worked during the winter have now run into rich leads:

CARIBOO.	
Bakerville division.....	\$120,700
Lightning creek division.....	76,500
Quesnelmouth ".....	62,400
Keithley creek ".....	63,100
CASSIAR.	
Laketon division.....	31,000
McDane creek.....	19,000
LILLOOET.	
Bridge river and its tributaries and branches of Fraser river.....	94,700
YALE.	
Similkameen division.....	117,500
Hope, Yale and Lytton.....	29,000
KOOTENAI.	
Wild Horse and other divisions in district.....	76,050
OMINECA.	
Vitalle creek and other divisions.....	10,500
SKEENA.	
Lorne creek.....	15,000
Total for year.....	\$730,650

The average number of miners employed during the year were 1056 whites and 1846 Chinese. The average wages realized by whites ranged from \$3.50 to \$6 per day, and for Chinese from \$2.50 to \$4 per day. The total estimated value of the yield of gold from 1858 to 1885, 27 years, is \$49,385,866. The highest yearly yield was in 1864, the total for that year being \$3,735,850, followed the following year with an output of \$3,491,205. The number of miners employed being 4400 and 4294 respectively, averaging in wages \$849 and \$813. The greatest average yearly earnings were in 1875, the approximate being \$1222 per man, and in 1868, \$902. The fewest number employed was in 1882, the total being 1838. The lowest average earnings was last year, showing only \$246 per man. The value of gold exported for the year 1885 was \$594,782.

TIN IN WASHINGTON TERRITORY.—The discovery of tin was made this spring by a rancher living on Oyster Bay, about 12 miles west of Olympia. In his prospecting tours he struck some ore in the foothills back of his ranch, which he had assayed. The assayer reported that the ore contained a sufficient percentage of tin to warrant further investigation of the find. The discoverer proposes to ascertain the extent of the ore.—*Seattle Times.*

### Stamp Mills and Chlorination Works.

The following paper, lately read before the American Institute of Mining Engineers, is entitled "Notes on the Stamp Mills and Chlorination Works of the Plymouth Consolidated Gold Mining Company, Amador County, Cal.," and was read by Geo. W. Small, E. M., of Oconomowoc, Wis.:

The ore, as it is raised from the mine, has an average assay value of \$11 per ton, chiefly in the form of free gold. All the ore goes directly to the stamp mills, of which there are two. The older and larger mill contains 16 batteries of 5 stamps each, with one Frue vanner to each battery. The new mill has 8 batteries of 5 stamps and two Frues to each battery. The large mill is driven by Leffel turbine wheels, with a pressure of 80 feet and a consumption of 600 miner's inches of water. The smaller mill is driven by "hardy-gurdy" wheels, with a pressure of about 550 feet and a consumption of 150 inches of water.

At both mills the tailings from the stamps pass over about 20 feet of plates on their way to the Frues. In each set of plates the first or upper one is copper; the rest are so-called silver plates.

The bullion from the stamps is about 800 fine in gold and 200 in silver.

#### The Concentrates

From the Frues average from  $1\frac{1}{2}$  to  $1\frac{1}{4}$  per cent of the ore stamped. They very rarely exceed two per cent. I was unable to get the exact assay value of the concentrates, but it is said to vary between \$100 and \$200 per ton.

The concentrates are treated at the chlorination works at the rate of 160 tons per month. The capacity of the works is somewhat greater than this, but as the supply of concentrates is limited it is not deemed advisable to work them up any faster.

Care is taken to keep the concentrates always damp until they are put into the roasting furnace. If this is not done, a decomposition of the pyrites begins, forming lumps which do not roast, and which consequently cause a loss of gold in the residues from leaching.

A *Fortsehaufungs-ofen* is used for roasting. Its dimensions, including fire-box, are 12' x 80'. The hearth is one continuous plane, but the charges, of which there are three in the furnace at one time, are kept entirely separate. The furnace-men call the three compartments the "drying," the "burning" and the "cooking" compartments. In the middle, or "burning," compartment the ore is spread out very thin and occupies about double the space of either of the other compartments.

#### The Furnace

Is worked by eight-hour shifts, one man on each shift, and one charge is drawn and a new one added in each shift. The charges weigh 2400 pounds and carry about 10 per cent of moisture. The ore averages about 20 per cent in sulphur, and just before the sulphur ceases flaming (in the second division of the furnace) 18 pounds, or three-fourths per cent, of salt is added to the charge.

The roasted ore from each shift is kept by itself on the cooling floor until a tankful (about four tons) has accumulated from a single man's shift; then that lot is worked by itself. This enables the person in charge the better to control the roasting; for, if only one lot out of the three is bad, it is presumable that the fault lies with the workman, but if all three are bad the probabilities are that there has been a material change in the character of the ore, and the roasting process must be altered accordingly.

#### The Vats for Chloridizing

The roasted ore are nine feet in diameter by three feet in height, and are four in number. They are slightly inclined, so that they will drain completely. The bottom of each tank is occupied by a filter about six inches thick, composed as follows: Light strips of three-quarter-inch wood are first laid in the bottom of the tank at intervals of about one foot. Across these strips are laid six-inch boards, leaving cracks of an inch or more between the boards. On top of this loose floor are placed coarse lumps of quartz, and on top of this again finer quartz material, until a total depth of about five or six inches is obtained. Finally, this "sand-filter" is covered by another loose floor, the boards lying crosswise to the loose floor beneath, and pretty close together. This upper floor is intended merely to furnish a shoveling surface, so as to permit the removal of the leached ore from the tanks without disturbing the filter.

The ore to be chloridized must be damp (about six per cent moisture). The working test is to take a handful of the ore and squeeze it, then open the hand, and if the lump immediately begins to crumble and fall apart (not run) the ore has the requisite amount of moisture.

#### The Leaching.

The damp ore is screened into the tanks, so that it will lie as loosely as possible, and facilitate the penetration of the chlorine gas. A coarse screen of one-half inch mesh is used for this purpose.

The tanks are only filled up to within about three inches of the top. This is to insure that the entire contents of the tank are covered by water in the subsequent leaching, otherwise there will be great difficulty in washing out all the soluble gold.

As soon as the tanks are filled as stated, they are ready for the introduction of the chlorine gas. This is introduced into the bottom of the tank from two opposite sides, and is continued until ammonia held over the ore gives off dense fumes of ammonium chloride. This usually takes about four hours. When this point is reached, covers are placed on the tanks and the cracks are luted with a mixture of leached ore, bran and water. The gas-generators, of which there are two employed at one time in charging a tank, are allowed to work on until they are exhausted; then they are disconnected and the holes in the tank are plugged.

The tank is usually charged with gas in the morning, and is left standing for two days. On the third day the ore is leached. The tank is first filled with water and allowed to stand a few minutes, so that the water may penetrate all the ore. If no more water is absorbed, the liquor is drawn off at the bottom, care being taken to keep the tank full of water during the entire operation, which takes from four to five hours.

In charging the tank, a gunny-sack is laid on top of the ore, where the wash-water is afterward to be introduced, in order to better distribute the water in the tank and prevent its washing and packing the ore.

#### The Liquor from the Leaching-Vats

Is conducted to settling or storage tanks, and about 40 pounds of sulphuric acid (66° B.) is added. (Experience has shown this addition of acid to be advantageous in obtaining a clean product in the subsequent precipitation. The chemical reaction is, however, by no means clear.) It is usually allowed to stand for 24 hours, but two hours are quite sufficient. It is then run into precipitating tanks, and the gold is precipitated by a solution of sulphate of iron. The iron solution is added until, after stirring, a further addition produces no purple color. After the gold is precipitated it is allowed to stand two or, if convenient, three days to settle; then the supernatant liquor is drawn off with siphons into a second settling-tank, where any gold that may have been drawn off by the siphons has a second opportunity to settle. The liquor stands in this tank until it is necessary to run it off to make room for another charge. Very little gold is found in this tank, and it is therefore only cleaned out once during the year. In the meantime, fresh liquor has been run into the precipitating-tanks upon the gold already precipitated there. In this way the gold is allowed to accumulate until the semi-monthly cleanup. Except when it is necessary to have them open, the precipitating-tanks are kept covered and locked.

#### In Making the Cleanup

The supernatant liquor is siphoned off, the gold gathered up and placed in a filter of punched iron, lined with a sheet of ordinary filter-paper, and washed with water until all the acid and iron salts are removed. It is then dried, melted in crucibles and cast into bars.

The works extract from 95 to 96 per cent of the assay value of the concentrated sulphides. Two men, on day shift, attend to all the work of handling the ore after it is washed (the leaching, etc.). The head man receives \$3, the other \$2.50 per day. Owing to the limited amount of ore allotted to the works, only three tankfuls are leached every four days. The men, however, are employed steadily.

The sulphate of iron is manufactured on the spot. For this purpose, an ordinary wooden tank about 4 feet by 4 feet, standing outside the building, in the open air, is used. The tank is kept full of water and supplied with old scrap-iron *ad libitum*, and for each charge to be precipitated about 40 pounds of acid is added to the tank.

The precipitating-tanks, which are of wood, are protected from the action of the acids by a coating of "paraffine paint."

#### Cost.

I append an itemized statement of the cost of handling the ore. The basis of figuring is 100 tons of ore per month of 30 days. Consumption of chemicals in the leaching department, 24 days in each month:

ROASTING.	
Three men, at \$2 50 per day for 30 days.....	\$225 00
12 cords wood at \$4.25 ".....	223 13
54 lbs. salt at $\frac{1}{2}$ cent, ".....	12 15
	\$460 28
GENERATOR.	
The charge is manganese, 30 lbs.; salt, 84 lbs.; sulphuric acid, 60 lbs.; therefore, for two gen. rators:	
Manganese, 60 lbs. per day, 24 days, at \$47 per ton.....	\$33 84
Salt, 68 lbs. per day, 24 days, at \$15 per ton.....	12 24
Acid, 120 lbs. per day, 24 days, at \$60 per ton.....	86 40
	132 48
Acid for settling-tanks (40 lbs.), and for sulphate of iron manufacture (40 lbs.), 24 days.....	57 60
Wages of leachers, at \$5.50, for 30 days.....	165 00
Salary of foreman.....	125 00
Total.....	\$940 36
Or, per ton of concentrates, \$9.40 3-10.	

PROSPECTORS IN ALASKA.—A report coming from Juneau that a number of mining men and others who have recently flocked to that town from the lower coast, intended returning to their homes by the *Mexico*, having been unable to obtain employment, and not having the means themselves to remain in Alaska without it, reminds us to repeat, what has been hereto-

fore stated in the *Alaskan's* answers to inquiries that no man should come to this country without the means to sustain himself for some time. There is work here to do, and a good deal of it, but there is no great demand for labor, outside of that which is already employed. The companies and individuals doing business are generally supplied with all the help they need, and in most cases have supernumeraries from whom to draw their extra labor when required. Prospecting is laborious and expensive, and a man should come with a sure situation, or the means to invest in something that will pay if successful.—*Alaskan.*

### Optimism of Miners.

In remarking upon certain objectionable practices in connection with mining, the *Chronicle* says: First, there is the habit of exaggeration so prevalent with the miner. He loves to deal in hyperbole. He sees things, if sometimes a little dim and shadowy, always large. If it is a silver-bearing lode, he has discovered it is invariably a second Comstock. If a vein of auriferous quartz, it is the greatest gold mine in the world, a veritable bonanza, the biggest thing out. The ledge, in either case, is of monster proportions—is, in fact, the dominating vein, the mother lode of the district. The ore goes into the thousands and pays from the grass-roots down. In short, the deposit is simply a mint and there's millions in it. Such is the manner of speech the professional prospector employs in describing his latest discovery, and he expects you will give him patient audience and believe all he tells you!

It is to little purpose you reason with this man of the big finds, reminding him how many "second Comstocks" and "greatest gold mines in the world" he has already discovered and reported to his friends. He is not to be rebuffed by this kind of talk, nor can you work his discomfiture by recalling his former mistakes or even convicting him of inconsistencies and fraud, and this for the reason that he does not believe he has been guilty of either. He has thought over these things within himself, and talked them over with his companions, until he is persuaded they are true, and having so deceived himself, he is now in the prime condition for proceeding with the work of deceiving others. Nor is this a mere fancy sketch or an exceptional thing. It frequently happens that the veteran miner, in his eagerness and haste, falls into honest yet wholly inexcusable errors, mistaking gangue for ore, pyrites for gold and copper stains for the chloride of silver.

Then there is another particular in which the explorer for mines is apt to show himself careless and inaccurate, to say the least. Ask one of these men about the wood and water supply of any district he has discovered or may have visited, and what is his answer? Always, "Plenty of these." If only he has found there water enough for his mustang or mule and wood enough to make a camp-fire, he assures you that the supply of both is all-sufficient. Now, when it is considered that, outside of California, there is hardly a mining district west of the Rocky mountains which is not deficient in these essential aids to mining, the impropriety of a statement so grossly misleading becomes amply apparent. Equally positive is he as to the excellence of the climate, the abundance of grass and the other natural resources of the district, all of which he is ready to asseverate are first-class, way up, and the like. It is statements and blunders like these, so barren of profit to the miner himself, yet so misleading to others, that have tended to bring both him and his calling into disrepute.

It is in the nature of mining to inspire loose and extravagant ideas, out of which has grown an equally loose and extravagant style of language. There is, however, for these idiosyncrasies of the miner some excuse. Being naturally hopeful and sanguine, he is apt to be credulous and hasty. Then, he has to grope much in the dark and deal largely with uncertainties. The outline of his facts, because of the obscurity that surrounds them, assumes often gigantic proportions. Things seen through the mist are apt to be magnified. But for all this, how can such a standing disappointment—a man who is so often wrong and so seldom right—hope to retain either the confidence or respect of others? It is the miners and the mining men themselves who have done the most to repel investments and scandalize the business.

And now that this industry is working its way once more to the front and likely soon to regain much of its former importance, the people and the press should exert themselves to prevent a repetition of the abuses that have so long been practiced in its name. The improvements lately made in mining pervade every branch of the business—they relate to its morale, its mechanism and its metallurgy. Work is being done better and cheaper now than ever before, ores that only a few years since were rejected as being too rebellious or too low grade to be handled being now worked with profit. There is less extravagance, less overstocking of properties and less speculation in shares now than formerly. Mines that for years had been neglected and fallen into decay are being rehabilitated, and even whole districts that had been partially abandoned are receiving increased attention. On every hand are to be seen such evidences of awakened interest as bespeak for this industry a more rapid growth and a better future.

## Passing Events.

The decision of the North Bloomfield Gravel Mining Company to make thorough experiments toward working their mine by the "elevator process" shows that they are in earnest in the matter of continuing work on their immense property, which has been closed down by reason of adverse decisions of the courts with regard to the debris. Should they succeed—as seems probable—in raising the gravel to the great height proposed by the hydraulic elevators, their success will go far toward furnishing a solution to the debris question, since they will only work bottom gravel and can impound the comparatively small amount of tailings they will make.

The fact that the Douglas Island mine is sending down from \$75,000 to \$95,000 per month in gold is attracting attention to the low-grade ore propositions in Alaska. D. O. Mills, the capitalist, is now examining the mine personally.

This number commences Volume LIII of the MINING AND SCIENTIFIC PRESS, and affords a very good opportunity for new subscribers to send in their names. The paper is necessary for any one engaged in mining or mechanical work on this coast, and all such should be among its readers.

WM. H. CLARK, an old resident of Austin, and who was owner of valuable mining interests on Lander Hill, died last week.

## An Electrical Sluice-Box Amalgamator.

Edward Pike, of Salt Lake City, has devised certain attachments to an ordinary sluice-box or flume for saving fine gold, amalgam, etc., in which he claims that the amalgamation is not dependent on the mere specific gravity of the precious metals, but is a forced one, so as to save all the float gold as well as the coarser particles.

In any ordinary sluice-box or flume, at any suitable distance apart, say six feet or so, more or less, according to the fall of the box, riffles of upper rounded configuration are arranged across the bottom. Immediately below each of these riffles the bottom of the sluice-box is cut out for a distance of from one to about three feet in length, and a quicksilver-tight box projecting from and below the bottom of the sluice, and open above, is substituted for the cut-out portion. These boxes are of a reverse inclination to that of the sluice-box, varying in degree as the character of the ore changes, but in every instance being deeper at what may be termed their upper end, relatively to the sluice-box. Above each of these "false boxes," at the bottom of the riffles, and resting on cleats, secured to the sides of the sluice, is a double perforated plate, composed of duplicate plates of iron or copper, insulated from each other. This double plate is set inclining upward in the downward direction of the sluice, leaving a mouth opening at its raised end between the sluice and false box. The perforations in the double plate are preferably of increasing size below, to give a ready clearance and prevent clogging by clay, etc.

In the bottom of each false box is an insulated amalgamated copper plate. In these boxes the quicksilver is placed, and their upper and lower plates are insulated as described, when it is desired to use an electrical current to expedite and improve the work, the two plates being connected with the different parts of a battery. The riffles—of hollow plates or solid—have a rounded shape, and will give a force of fall that it is claimed will effectually secure the amalgamation of free gold by bringing it in contact with the quicksilver.

The boxes in the bottom of the sluice or flume are fixed ones, and the upper perforated plate and lower inclined one, with the quicksilver resting on the latter, will secure the necessary amalgamation, give a proper distribution of the sand over the surface of the amalgamating chambers, so as to save fine flour gold and amalgam. The inclined plate in the bottom of these false boxes may be used for concentrating the ores, and the mouths and position or arrangement of said fixed boxes with their inclined bottoms will serve to provide for the apparatus clearing itself of dirt falling through into it. The succession of amalgamating chambers and plates is intended to be specially serviceable where the stream is a heavy one, as any precious metal that failed to go through the first perforated plate would go through the next succeeding ones. Instead of the upper perforated plate being set to incline reversely to the general bottom of the sluice, it may be set parallel if desired.

When electricity is applied to promote the amalgamation, the double plate, by being made a compound one, as described, and connected, as regards its lower insulated plate, directly or indirectly with the positive pole of the battery and the bottom amalgamated plate with the negative pole, the electric current will be confined to the stream passing through the fixed boxes and not be scattered or have its force impaired by passing through the water in the entire box. When the stream is passing through the fixed boxes, and the lower plate is charged with negative electricity and the lower one of the upper double plates with positive electricity, the precious metals are attracted to the negative, the bottom plate, and the base, etc., are attracted by the lower upper one of the plates, and the water falling through completes the circuit. Only certain of the boxes may be charged, or the whole of them, as may be desired.

E. N. RIOTTE, the well-known mining man, formerly of San Francisco, but now of New York, has made a flying trip to this coast, examining some Nevada mines. He was in this city a few days.

A NUGGET worth \$216 has been picked up at Green Valley, El Dorado county.

## Metallurgical Works.

One of the principal reasons Colorado has made such rapid strides in its mining development is that there are so many reduction works all over the State. Some of these are on a very large scale and complete in all their appointments. Miners have been able to work their own properties and sell their ore to these works to good advantage. Most of the other States and Territories have suffered from lack of these facilities. It is only of late in this State that the Selby Smelting and Lead Co. have commenced to purchase all classes of ores. Arizona is entirely without any central metallurgical point. New Mexico and Oregon are no better off. Idaho and Montana ship more or less to Salt Lake and to Colorado. Nevada outlying districts ship to Denver, to Salt Lake or to Port Costa.

Nevada is particularly unfortunate in this respect. There are many districts without any facilities for working ores; and there are other districts with private mills, but outside miners cannot get their ore worked. The great need of that State is metallurgical works where all grades of ore can be sold and worked.

Probably the best point in Nevada to establish large metallurgical works to treat all classes of ores is Reno. The railroads center there, and there is abundance of water power, the Truckee river running through the town. Reno is now the center of the educational interests of the State, and its prosperity and that of the surrounding country would be greatly enhanced if metallurgical works on a large scale were established. Peavine, Pyramid, Paradise and many other districts would ship their ore, concentrates, etc., there, if they could get them worked. The many districts down along the line of the Carson & Colorado Railroad would doubtless ship there if facilities were offered. No mining country has any larger extent of low-grade ore propositions than Nevada, and it is these ores that the miners want worked. There is no point between the Rocky and Sierra Nevada ranges that offers better facilities for reduction works than Reno. It will be the commercial town of the great country between these two ranges and should be the metallurgical center as well.

## Quartz Mining and Debris.

The fear among some quartz miners that court decisions and legislation on the mining debris question would seriously affect them, was never very well grounded. Whatever extremists may have urged on this point would hardly have been verified when it came to the test. The muddying of a stream from the tailings of a quartz mill would be of such small importance that it would be difficult to obtain injunctions against them. The largest quartz mill in the State could impound its tailings in a few acres of land. Still some of the quartz miners of California thought it worth while to send a man to Washington in their interests, to prevent any clause going in the River and Harbor Bill which might interfere with quartz mining.

The bill, making appropriations for the improvements of rivers and harbors (including spring branches) in the United States, as it passed the House of Representatives, provided that no rock, dirt, sand, debris or anything else should run from mineral lands into any position or place from which such rock, sand, etc., might eventually be washed into any navigable river. This provision, literally construed, would prevent any kind of work whatever being done on mineral land. There was also a provision inserted that the war power of the United States should prosecute the people working on mineral lands.

The bill went to the Senate and was referred to the Committee on Commerce, where it was changed so that no reference to quartz mining was made. The Senate Committee on Commerce has also struck out of the bill the clause making it the duty of the Secretary of War to prosecute those who violate the slickens provision.

WILLIAM PATTERSON, one of the oldest miners in Tuolumne county, died suddenly at Tuttletown, last week. He was one of the very few old-time prospectors left in Tuolumne. He worked and toiled meeting all the vicissitudes of the prospector and miner. His life has closed at 76 years.

## New Hand-Power Rock-Drill.

Wm. Brady and Daniel Fitzpatrick, of Virginia City, Nevada, have just obtained, through the MINING AND SCIENTIFIC PRESS Patent Agency, a patent on a new hand-power rock-drill of that class in which the drill is carried by a sliding carriage, and is actuated by means of cams and a spring. A frame is made, in the sides of which is mounted the sliding carriage. The supporting pillar or bar is pivoted in a suitable clamping device which is itself pivoted to the frame, whereby the drill may be turned in any direction or to any angle. This supporting pillar is adapted to be tightened against the walls of the drift by a screw.

Mounted longitudinally on the carriage is the drill spindle, the center of which is provided with two collars and passes loosely through a crossbar, the ends of which bar extend within and are guided by grooves made in the sides of the carriage. There is a strong spiral spring by which the spindle is thrown forward. Upon the forward end of the spindle is a chuck, consisting of a chambered barrel, in the center of which are seated two jaws, between which the shank of the drill bit is fitted. A set screw sets up the jaws to clamp the drill bit. This chuck is adapted to receive the drill bits just as they are, without the expense of turning or dressing them.

Mounted on the sides of the carriage, forward of the grooves in said carriage, are short shafts connected by a link whereby they are strengthened. Pivoted or jointed to ears upon the shafts are the operating cams, which are so pivoted to their bearings as to have a motion on their pivots but in one direction. One of these cams is simply a gravitating one, adapted to fall to its position, while the other is provided with an arm and a spring whereby it is raised positively to its position. The gravitating cam is located in such a position that when below the shaft, against the anti-friction roller or sleeve on which it bears, it is adapted as its shaft is lowered to force the crossbar back, thus throwing the drill-spindle backward against its spring. While this movement is taking place, the spring-cam on the other side is rising to a vertical position. When the crossbar is released from the gravitating cam, the drill is thrown forward to deliver its blow. The movement of the short shafts in the reverse direction causes the spring-cam to bear backward against the sleeve on its side of the crossbar, thus forcing it back and allowing, just before it releases it, the gravitating cam to drop by the crossbar to its original position. Then the spring-cam releases the crossbar and the drill springs forward to deliver its blow.

The movement in the first direction causes the gravitating cam to operate as described in the first instance while the spring-cam is pressing under the crossbar, until just before the gravitating cam releases its impingement the spring can be released, when it springs to its upright position. In this way, by the oscillation of the shafts, the drill is forced back and is thrown forward to its work. There are long hand-levers, or two men work the drill together, one on each side. Means are provided to rotate the drill, and the carriage, with its drill mechanism, is easily advanced by a screw and crank.

## Occurrence of Gold.

Many persons have an idea that gold, being the "King of Metals," and scarce, is found in but few places in the world. The United States, Australia and Russia are the principal producers, but it is widely disseminated in many parts of the world. The following are localities in which gold is found in workable quantities:

Africa.—Northern, Southern and Western.  
North America.—Alaska, British America, Costa Rica, Guatemala, Honduras, Mexico, Nicaragua, United States, West Indies.  
South America.—Argentina Republic, Bolivia, Brazil, Chili, United States of Colombia, Ecuador, British Guiana, Dutch Guiana, French Guiana, Paraguay, Patagonia, Peru, Uruguay, Venezuela.  
Australasia.—New Caledonia, New Guinea, New South Wales, New Zealand, Queensland, South Australia, Tasmania, Timor, Victoria, Western Australia.  
Asia.—Afghanistan, Anam, Cambodia, Cochinchina and Siam, Arabia, Assam, Banca, Borneo, Burma, Celebes, Ceylon, China, Corea,

India, Japan, Kashmir, Ladak, Malay Peninsula, Persia, Philippines, Russia in Asia, Sumatra, Thibet, Trans-Caucasus, Turkistan, Turkey in Asia.

Europe.—Austria-Hungary, France, Germany, Great Britain, Greece, Iceland, Italy, Norway, Portugal, Roumania, Russia in Europe, Servia, Spain, Sweden, Switzerland, Turkey in Europe.

### Mining Accidents.

The dead body of John Bohm was found at the head of the incline of the Hamilton Consolidated mine, north of the Lady Bryan, in Howery district, Nev. One hand grasped a miner's candlestick and the other held a tobacco pipe. It is supposed that death ensued from asphyxiation caused by inhaling the fumes of powder from a blast that had been recently fired in the breast of the drift. The mine is in an isolated locality, and Bohm's life is supposed to have been extinct several days before the discovery of the remains.

On Friday last another accident occurred at the Idaho mine, Grass Valley, in which one man lost his life and another received severe injuries. Three men, Enoch Holland, Harry Bennett and Joseph Batten, had a contract for sinking the shaft on the 1700-foot level of the mine. Holland was not able to go to work and Bennett took his place at the drill. Bennett and Batten were alone in the bottom of the shaft. They had prepared three blasts and had gone off some distance to be out of the way of the flying rock. Two of the three shots exploded, and after waiting fully three-quarters of an hour for the third one to explode, they went back to see what the trouble was. They found that some large pieces of quartz had fallen over the top of that charge, and while removing the last piece with a gouge, tipped with a piece of clay, the explosion occurred. Bennett, who was right over it, was hurled against the side of the shaft with great force, crushing in the back of his head and otherwise bruising his back. He was killed instantly, never uttering a sound. Batten was thrown into a pool of water. His left eye was torn out and his left arm fearfully bruised. With great difficulty he was able to drag himself to the air pipe, where he gave the signal of distress, which was responded to by his fellow-workmen, whom he told to go and find Bennett, who was found partly covered by debris and dead.

### Crystal Alum.

A new method of obtaining crystal alum from kaolin, bauxite or other aluminous material has recently been patented. A commercial alum, free from iron and fit for dyeing, calico-printing, etc., is obtained.

The kaolin, bauxite, or other aluminous material employed is first treated with sulphuric acid according to any of the usual methods for producing from such raw materials a ferruginous solution of alumina. This solution of sulphate of alumina and iron is allowed to settle, or otherwise cleared. The cleared solution is removed into a suitable vessel, and is treated with an oxidizing agent, to transform ferrous oxide into ferric oxide. The quantity of oxidizing agent is governed by the quantity of protosulphate in solution being treated. The oxidizing process is to be carried on to the point at which no protoxide of iron can be detected in the solution. In carrying out this method the inventor preferably, though not necessarily, employs solution in a hot condition. After the iron has been brought to the state of a peroxide, and the impurities settled out, the clear liquor is drawn off. In this clear liquor there is now added such a quantity of sulphate of potash, or sulphate of ammonia, or sulphate of soda, as is required to form a compound consisting of sulphate of alumina, and a sulphate of one or more of said alkalis. This solution, if necessary, is boiled down to the required density to form crystals, is allowed to cool, and left to crystallize. The persulphate of iron which has been formed by this method, being more soluble than the protosulphate of iron, remains in the mother liquor, with the result that crystal alum free, or nearly free, from iron is produced.

ROSS E. BROWNE has resigned his position in the University of California, and will hereafter follow his profession of civil and mining engineer.

### Foundry Notes.

The condition of the strike at the Union Iron Works is best explained by the following correspondence:

THE REPRESENTATIVE COUNCIL OF  
IRON TRADES,  
SAN FRANCISCO, June 26, 1886.

To the Managers of the Union Iron Works—GENTLEMEN: At a meeting of the council, held last evening, the following preamble was adopted:

It being for the interest of employer and employee alike that all difficulties and disagreements between them should be as speedily settled as possible, so that work may be continued with as little friction as is consistent with their joint interests, to that end we therefore propose that a committee of five from this council shall meet a similar committee from the Union Iron Works Company, and that the 10 meet and choose one member who is not interested on either side, and that the committee of 11 arbitrate the present difficulty. The committee appointed at the previous meeting was also instructed, and after one day's notice of time and place are willing to meet representatives of your firm for the purpose of carrying into effect the spirit of the above preamble. Respectfully submitted,

S. MCKEE,  
Sec'y pro tem. Ex. Com.

Yesterday the answer was returned as follows:

UNION IRON WORKS,  
OFFICE, 401 MARKET STREET,  
SAN FRANCISCO, June 28, 1886.

Samuel McKee, Esq., Secretary pro tem.  
Executive Committee—DEAR SIR: We acknowl-

### Banded Structure in a Gold Vein.

Mr. Charles M. Rolker puts on record before the American Institute of Mining Engineers a sketch of a vein examined by him in Honduras, Central America, which exhibits a well-marked banded structure. The illustration is of natural size. The vein traverses trachytic porphyry; it is from three to four inches wide. The central band, *a*, is of white quartz one inch wide. It is full of cavities and vugs, lined with quartz crystals, and its mass is largely stained with hydrated oxide of iron, in which is a heavy sprinkling of coarse gold, indicated by dots and shading in the section. On each side of *a* is a band of pure white crystalline quartz, *b*, three-eighths to one-half inch wide, showing incomplete crystals in radial forms. This band contains no gold. Next follows a band, *c*, on each side of *b*, from three-eighths to one-half inch wide. Through its center runs a fine fissure, lined with interlocking quartz crystals, on each side of which is bluish "ribbon-quartz," containing very finely impregnated gold. The outside band, *d*, also varies from one-half to three-eighths inch in width, and is made up of compact but columnar quartz, the outside face of which (toward the wall-rock) is frequently lined with fine quartz crystals. The columnar quartz is more or less frequently stained yellow by hydrated oxide of iron, and it contains some very fine but light gold. *P, P*, are

GOLD-BEARING VEIN IN HONDURAS, SHOWING BANDED STRUCTURE

edge the receipt of your communication informing us that a Committee of Arbitration had been appointed to meet the representatives of this company to arbitrate on the difference between us. We fail to see how it would be possible to arbitrate on the issue you have raised in demanding the discharge of certain of our workmen because they do not belong to your federation. If it were a question of wages or hours, workshop rules or practice, we would be most ready to meet you and endeavor to arrive at a just settlement, but what you demand is not ours to give. The right of every man to honestly earn his living is his own right, and is secured to him by a higher power than either yours or ours. Suppose we could arbitrate on such a question and the arbitrators should allow that you had the right to demand the discharge of any number of men from our works because they might be obnoxious to some union in your federation, and that you had the right to withdraw all of your men from our works. Should the demand not be complied with, then the same process of arbitration would of necessity grant us the same rights, by which we could demand the expulsion of any member of your federation who might from any cause be obnoxious to us, and that we should have the right to lock out all union men in our employ if our demands were not complied with.

The demand you have made is unjust, and a compliance with it, either in whole or in part, would be a criminal act on our part. A wrong could never be arbitrated into a right. We can therefore see no way to a settlement, except by a frank withdrawal of your demand.

Yours truly,  
G. W. DICKIE, Manager.

THE electric fire alarm system in Napa is entirely completed now, and is found to work perfectly. The system cost nearly \$1000.

walls of trachytic porphyry. The whole vein matter has a tendency to split off in slabs, in a vertical direction, the full width of the vein. The section illustrated represents, of course, an exceptionally rich piece from one of the bonanzas which occur as nests and isolated, irregular bodies in the vein. A slab similar to the one illustrated, weighing two and a half pounds, panned out over one and one-fourth ounces of gold.

**PNEUMATIC LIGHTING.**—A new method of lighting, called the pneumatic system, has been described by a Frenchman, M. Bender. He employs the fatty residues obtained from the rectification of crude mineral oils, through which he passes a current of air. The air takes up a definite quantity of this hydro-carbon and the flame produced is very brilliant, giving off no smoke. Cheapness and immunity from explosions are the advantages claimed.

**AN AEROLITE HOAX.**—The reported finding of the great meteorite in Washington county, Pa., turns out to be a fiction, and must be relegated to the same shelf with the famous moon hoax which the N. Y. Sun perpetrated some 50 years ago.

THE annual financial statement of the North Star mine, Grass Valley, for the fiscal year ending April 30th, shows receipts amounting to \$129,996.69 and disbursements of \$115,220, leaving a cash balance on hand of \$14,766.69.

### Assaying With the Horn Spoon—No. 1.

[Written for the Press by ELBERT C. VAN BLARCOM.]

The sample should first be ground to a fine powder—the finer the grinding the more accurate will be the result. If there is no mortar at hand, in which to grind the ore, select a flat rock with a surface about 18 inches square, and another smaller rock weighing about 10 pounds, of convenient shape, so that it can be firmly grasped with both hands. Where they can be had these rocks should be of a hard silicious character; softer rock may be used, but the grinding will take a longer time. It is not advisable to use as grinding rocks any that contain mineral, as they are liable to enrich the sample.

Place the sample on the large flat rock and reduce it to fragments by a few quick blows from the smaller stone. Now take the smaller stone firmly in both hands and grind the fragments to a powder, grinding a small portion of about one ounce at a time.

Any one who has never tried this method will be surprised at the rapidity with which the grinding is effected. Transfer the sample to the horn, taking care to clean the grinding rocks thoroughly. If the sample contains sulphurets these will break up more readily than the gangue and fill up the small cracks and interstices in the grinding rocks. A small stiff brush serves well to clean the grinding rocks.

The sample for assay should not fill the horn to within more than an inch of the rim. Take the horn containing the sample in the right hand, and gently submerge it in a vessel of water, or stream; with the fingers of the left hand thoroughly mix the sample with the water. When the sample has been thoroughly wet carefully withdraw the horn from the water, bringing the left-hand end of the horn out of the water last. During this operation the light earthy particles contained in the sample will rise to the top, and as the horn is withdrawn from the water they will flow off. This operation should be repeated two or three times, until nothing but the clean sand remains in the horn.

When the light matter has all been removed take the horn (having the sample covered with about half an inch of water) in the right hand, letting the weight bear on the third finger and balancing it with the thumb. After mixing the contents of the horn thoroughly with the fingers of the left hand, oscillate the horn in a right and left direction, at the same time giving it a slight up and down (a sort of shivering) motion with the third finger of the right hand. During this operation the left-hand end of the horn may be supported on the fingers of the left hand; the motion should all come from the right hand, the left hand simply serving as a support. By continuing this motion a few moments gravity will take the mineral particles to the bottom, while the lighter particles of gangue will remain on top. The sample should now be brought to the left-hand end of the horn, inclining the horn slightly to the left; allow the water to run off, after which remove with the left hand the upper portion of the sample from which the minerals will all have become separated.

The concentrating and removing of the barren particles should be continued until the amount of mineral can easily be seen. From the amount of mineral left, after concentrating, one can readily judge the approximate value of the ore.

A "horn" may be made by sawing in two, obliquely, any good-sized cow's horn. This will give an elliptical shaped vessel about two and a half inches deep, flaring off at either end.

Where the available horns are small, select the straightest one, split it lengthwise on the inside of the curve, lay it in hot ashes, and when it is thoroughly heated it can be molded into the desired shape.

To make one's self an expert in this method of assaying one should have fire assays of the sample made; knowing the fire assay and observing the yield from a given amount of ore, one will soon be able to judge very closely the values of ores.

In Mexico the horn is used almost exclusively, even as a test for value when the ore is to be purchased. Of our own knowledge we can say that we have known the assay by the horn, given us by a Mexican, to have been within one dollar of the same sample afterward assayed by the fire method.

## MECHANICAL PROGRESS.

## Reductions in the Cost of Steel Making.

A century ago or thereabouts all the steel used in England for the finest work, such as watch springs, the best swords, etc., was imported from India at a cost of from \$400 to \$500 per ton. English metallurgists, however, gradually improved in their manufacture and the cost of production until its cost was brought within reasonable limits and its quality equal to the best imported. In 1872 steel rails were sold at from \$80 to \$90 per ton. German, Italian and Belgian manufacturers are now competing in the markets of the world as low as \$17 to \$18 per ton for the same quality of steel. The wages for ingot-making in 1872, in England, were \$5.25; they are now as low as 75 cents. The wages then paid for rail-making were about \$5 per day; they are now about \$1.50 and less.

It will thus be seen that the workmen have contributed quite largely in the reduction of their wages to bring about this cheapening process. Of course, however, the reduction in cost is mainly due to improved machinery and furnace processes. Yet the English iron-master is still telling his workmen that they must submit to still lower wages if they would hope to successfully compete with the Belgians. They say that the workmen must accept lower wages and live more economically and masters must use better science and turn out better work, in order that the worker may live more cheaply.

In the fierce competition for the world's market for iron and steel the English manufacturers are evidently losing ground and the trade is gradually passing into the hands of the Belgians and Romans. Some of the leading iron-masters, Mr. Snell for example, seem to think that the English are getting behind in technical knowledge and machinery improvements. The gentleman named does not hesitate to say that "the Americans and Germans are more successful than we are." Still he is hopeful that England will yet gain her lost ground, and beat all other nations as she has ever heretofore done. But just how this is to be done does not appear to be very clear in his mind. One thing is certain: labor cannot submit to any further reduction without utter demoralization, and protection cannot avail to serve the foreign market. What then?

## An Immense Forging Press.

It has been increasingly evident for some years past that the large forgings required by modern engineers and artillerymen demand something better than the steam hammer for their manufacture. The requirements in this direction have advanced more rapidly than the means of production, and in only a few instances have manufacturers erected steam hammers of sufficient size to deal with steel ingots weighing upward of 50 tons. The great cost of installation of such large hammers has perhaps deterred steel-makers from making much advance, and, beside this, they have felt that the hydraulic press was more suitable for the production of large forgings. Except in two instances, however, the efforts made to substitute the hydraulic press for the steam hammer have met with only very partial success, owing to its slowness of action and want of adaptability to the variety of work which can be executed under a hammer. Seeing that the press has been proved to make the best forgings, further efforts are now being made, and there will shortly be three presses put to work in England.

The question of the quality of work, of course, outweighs every other consideration, but there are other reasons for the transition now in progress. The cost of installation is less in proportion to the weight of forgings made. The moderate height of a press permits the use of overhead traveling cranes, so that the furnaces, six or eight in number, can be arranged along the sides of the forge with one press to serve them all; whereas four furnaces with a swing crane to each are the practical limit in the case of a large hammer whose great height forbids the use of overhead travelers.

**ROLLING OUT IRON CHAINS.**—A firm in Chicago is getting ready to roll out a chain from a solid bar without having the pleasure of welding a single link, by passing the bar through a set of four rollers that squeeze it into a series of links all linked together into a chain. By this means a uniformity of strength is obtained without requiring any particular skill of the operator. The principle of forming the rollers and the process of rolling out a chain is similar in some respects to the method employed in casting the links and having them come out together in a chain from a mold. In the latter operation the flask is made to part equally in four ways, and the chain molded while the links are separated so as to divide the spaces equally between them, giving as little clearance as possible, which will not change their appearance perceptibly. The flask is divided, the chain removed, and one is cast in the mold. With this explanation an expert can understand how a piece of chain can be swaged out of a bar of iron in an analogous manner by means of four converging dies without difficulty. To produce a continuous chain in this way the dies must be made continuous by having them formed on the circumference of four rollers arranged with the dies distributed in equal di-

visions and the rollers driven by gear wheels so that the four parts of a link will meet accurately in place. Proper clearance must be given to the dies so as to allow the material to leave the matrix freely as the roll revolves. The manner of making the rolls for different sizes and shapes of chains are matters that present but very little difficulty to mechanical ingenuity. As the blank is carried forward between the rollers the dies partially press or swedge out the links at right angles to each other, breaking the fin or feather edge that is left on the inside of the links, which, after a thorough shuffling in a tumble barrel, come out highly finished and polished for the market.

**EXPERIMENTS IN IRON AND STEEL OXIDIZATION.**—A French metallurgist has recently made a series of experiments as to the comparative oxidizability of cast iron, steel and soft iron under the influences of moist air, sea water and acidulated water. It was found that with moist air the steel plates lost from three to four grammes weight in 20 days for every two square decimeters of surface. Chrome steel had a tendency to rust more, and tungstated steel less, than the ordinary carburized steel; cast iron lost only about half as much as the steel, and spiegeleisen less than gray iron. Sea water dissolves iron rapidly, and acts upon it more powerfully than on steel; most powerfully of all upon spiegeleisen. In nine days the steel plates with two square decimeters of surface lost from one gramme to two grammes, while phosphorized iron lost five grammes and spiegeleisen seven. Tempered steel was less affected than the same steel twice annealed; soft steel less than chrome steel, and tungstated steel less than the ordinary steel with the same proportion of carbon. Acidulated water dissolves cast iron much more rapidly than steel.

**A NEW GUN,** known as the Mefford gun, has recently been tested at the Washington Navy Yard. The gun is quite a novelty in its construction. The one on trial was small—only three-inch caliber. It is built up with two concentric cylinders, the inside one being of steel, the outside or re-enforce of cast iron, and a space for a non-compressible fluid between. The aggregate strength of the two cylinders is only about one-third that of the navy three-inch steel gun. The charges fired were the same as the regular charge of the navy gun, there being used one pound of powder and a seven-pound projectile. Between the discharges a stopcock was sprung to allow the fluid to flow out, to compensate for the expansion of the inside tube by heat, thereby taking the strain off the re-enforce. The last charge fired contained double the amount of powder—two pounds of powder—and the gun stood the strain well.

**BAD EFFECTS OF CEMENT ON IRON.**—A short time since, according to the *Sanitary News* of Chicago, a large water pipe on the fourth floor of the government building, in that city, burst, flooding the floor and badly damaging the ceiling of the third floor. It is thought that it was caused by the cement hardening, together with the jars caused by the workmen while repairing other parts of the work. In relaying the tiles on the floor it has been found necessary to replace much of the iron gas pipe with galvanized iron pipe, as the iron pipe had almost rusted away, while the galvanized iron pipe that was put in about nine years ago is almost as good as it was then, showing to advantage the lasting qualities of galvanized iron as compared with iron pipe when imbedded in cement. As the cement is so injurious, the pipe is being either incased in boxes or laid in gravel.

**TEMPERING BRASS.**—The assertion that "brass cannot be tempered" is met by a writer in *Mechanical Progress* with the following reply: "This differs with my daily experience. Brass, not hard by mixture but by compression, either rolling, hammering, wire-drawing or any other process which compresses the particles of metal, can be and is tempered regularly, just as easily and in the same manner as you would temper an equalized piece of hardened steel, viz., by heat. By placing a small piece of polished steel on the brass object to be tempered and applying the heat so as to affect equally the brass and steel, you will know by the color of the steel the temper of the brass, which by this process may be tempered in exact proportion to every shade of color of the steel."

**WEAR OF RAILS.**—The opinion has been expressed that newly-rolled rails wear more rapidly than old rails, and that all rails wear more rapidly when first laid down than they do after having been in use for a short time. The statement has not only not been established but cannot be established, for the direct contrary is true, says a competent authority. No doubt it is true enough, however, of many rails which get put in the track, for "after having been in use for a short time" they do not wear at all—being put away to rest in the scrap-heap.

**PREVENTING ANVIL NOISE.**—A correspondent of the *Scientific American*, referring to the several methods adopted for deadening the sound of anvils, suggests the following: It is advisable to set in lead or sand. I find by setting the anvil on a piece of plank, say two feet square, and hanging that by the corners to the wall above with small ropes, you will get scarcely any noise and no jar, and the anvil is as solid as if placed upon a block.

## SCIENTIFIC PROGRESS.

## Saccharine—The New Coal-Tar Sugar.

We have already made brief mention in this column of the discovery of a new sweet principle which has been obtained from coal-tar, and which is said to be 230 times sweeter than cane sugar. This new principle has been named saccharine. It was discovered by C. Fahlberg, a German chemist, but for a long time past a resident of this country. Its chemical name is benzoyl sulphonic imide. It presents the appearance of a white powder, and crystallizes from its aqueous solutions in short, thick prisms. Unlike sugar, it dissolves readily in alcohol. It melts at 200 degrees Centigrade. Its taste in largely diluted solutions is intensely sweet. One part will give a very sweet taste to 10,000 parts of water. When taken into the stomach in quantities in which it is added to produce the ordinary sweetness of sugar, it has no injurious effect whatever on the human system. It has been given to dogs in quantities equal to two and a quarter pounds of sugar a day, without producing any perceptible ill effect on the animal.

It has been given to patients suffering from diabetes without their feeling any inconvenience from its use. Physicians will no doubt be pleased to find a sweetening substance by means of which diabetic persons may enjoy food that has heretofore not been admissible in their case.

Saccharine does not belong to the class of carbohydrates, and does not possess nutritious properties. Dr. Fahlberg combines glucose with starch sugar, and thus obtains a compound which he calls "dextro-saccharine," which, as far as the taste is concerned, is scarcely distinguishable from the best sugar. The quantity of "saccharine" used is in the proportion of one part to from 1000 to 2000 parts of glucose. Now, if we look at the price of saccharine, which is at present about \$12 a pound, we shall find that even at this price such a mixture would be very considerably cheaper than real sugar; but we must bear in mind the fact that there is great likelihood of the process of manufacture of saccharine being considerably cheapened; the expensive phosphorus-pentachloride may probably be replaced by a cheaper compound, etc.

The solubility of saccharine in ether might probably be useful in detecting its presence when mixed with sugar. This discovery offers a new and important use for coal-tar, and saccharine promises to become a very important rival to sugar.

In its manufacture, Fahlberg commences with toluene, a hydrocarbon, present in coal-tar. This toluene,  $C_6H_5(CH_3)$ , he converts into its two monosulphonic acids, and transforms these by treating them with phosphorus-pentachloride ( $PCl_5$ ) into the corresponding toluene-sulphonic chlorides. Of these two toluene-sulphonic chlorides, namely, the para and the ortho, only the ortho compound, which is liquid (the other being solid), is suitable for the production of saccharine. By the introduction of the amido group of ammonia, this ortho-toluene-sulphonic-chloride is then converted into ortho-toluene-sulphamide, which finally yields, by oxidation, the benzoyl sulphonic imide or saccharine.

**LUMINOUS CONCRETE.**—A method of utilizing the luminous powder prepared mainly as a sulphide of calcium for admixture with cements, plaster of Paris, and concrete has been recently invented by E. Ormerod and W. C. Horne, of London, the object being to prepare the articles with a self-contained phosphorescent property instead of coating them with luminous paint. The patentees take of cement, Keen's Portland or other suitable make, in varying proportions, as, for instance, two pounds to five pounds to one pound of the luminous powder; mix the same with water, then mold to required shape, or lay it on to ceilings or walls by means of a trowel. The patentees attach importance to placing the molded articles, as soon as they have been dried, in a bath of paraffine wax and benzoline or other suitable weather or water proofing substance. In the case of using the luminous cement upon a wall or ceiling, they sponge or brush the surface over with a solution of paraffine wax and benzoline or other suitable damp-proofing solution. The uses of a luminous cement are manifold: e. g., for the garden, as edging to paths and carriage drives, for guides at the entrance gates of drives, insides of stables, the base of balustrades, or their entirety. For roads—as luminous beacons at corners of country lanes, and at the ends of bridges, walls, and curbs of footpaths. For docks—for edging of piers and wharves. In short, for any places where the light of day will sufficiently excite the phosphorescent property as to render the cement or concrete work luminous by night.

**DEVELOPMENT OF THE LEAF OF THE EUCALYPTUS.**—Some instructive experiments have been made by Mr. S. Groszlik on the development of the leaf of *Eucalyptus globulus*. He finds that in the youngest stage the tissue of the leaf between the epidermis, with the exception of the vascular bundles, consists of a uniform tissue composed of cells equal in diameter in each direction, which the author calls primitive mesophyll. If the leaves are forced to remain in the horizontal position, they develop the usual leaf structure of palisade cells on the upper and spongy tissue on the lower side of the leaf; but

if the leaves assume the vertical position, palisade cells are developed on both sides of the leaf next to the epidermis. He therefore arrives at the conclusion that there is in leaves a tissue which is capable of differentiation, and that under the influence of light there is a tendency to form palisade tissue, while shade favors the formation of spongy tissue.

**MICROSCOPIC METALLURGY.**—It is claimed that, under a powerful microscope, the relative conditions of the iron and carbon particles in steel may be definitely determined. The fine granular appearance of steel, so well known when closely examined under the microscope, is found to consist of a multitude of minute cells, the nucleus of each cell being formed of iron, and carbon forming the outer skin. The statement is, that the investigators who have made this interesting discovery expect to be able, in the course of further researches, to demonstrate the position that impurities, such as phosphorus, sulphur and silicon, held in the structure of steel, and which has been so long the subject of experiment. It is thought that this line of inquiry will be likely to produce important results, in showing exactly the structural changes that take place in steel, under conditions approximate to what it has to endure in ordinary service—there being at present but little real knowledge respecting the changes that take place in the internal arrangement of metals under such circumstances.

**BEAUTIFUL WHITE ALLOYS.**—The beautiful white alloys now made of aluminum and silver are said to be much harder than those from pure aluminum, and, on this account, they take a much higher polish, and at the same time are preferable to the silver copper alloys, for the reason that they are unchangeable in air and retain their white color. It was some time ago proposed, therefore, no longer to alloy the world's coin with copper, but with aluminum, thus rendering them far more durable, and their white color being retained after long-continued use. It appears that according to the quantities of aluminum added, the alloys possess very varying physical characteristics. Thus, an alloy consisting of 100 parts aluminum and five parts silver differs but little from the pure aluminum, yet it is much harder and assumes a higher polish; an alloy consisting of 169 parts aluminum and five of silver possesses a very remarkable degree of elasticity, and an alloy of equal parts of aluminum and silver rivals bronze in hardness.

**MARKINGS OF ANIMALS.**—Eimer advances the view that the markings on animals were primitively longitudinal stripes that have subsequently broken up to form dots, and these fusing to form transverse rings. This view is supported by the ontogeny of many animals. Dr. Haacke controverts this view from the study of an Australian fish *Helotes Scotus*. In this species the adult is marked with eight longitudinal black bands. Young specimens have, in addition, a row of clear, transverse bands, which disappear when the fish attains maturity.

**THUNDER, LIGHTNING AND RAIN.**—Meteorologists have found that there can be no thunder and lightning without rain. When thunder is heard beneath a clear sky, the reports must either come from distant clouds or be the result of some other cause than a discharge of electricity. Harvest or heat lightning is produced by a distant storm. Thunder seldom ever accompanies heat lightning, the sound reaches only 12 miles, while lightning is often seen by reflection upon nearer clouds, at a much greater distance.

**THE WATER OF TREES.**—In the latitude of New York, Prof. P. D. Penhallow has found the proportion of water in trees and shrubs to vary according to these general laws: 1. The water in woody plants is not constant for all seasons, and depends upon conditions of growth. 2. It is in greatest amount late in May or early in June, and least in January. 3. It is in greatest proportion in the sap wood; least in that which is older. 4. When plants grow most rapidly they have most water.

The cause of single and double rainbows is due to the combined reflection and refraction of the sun's rays from drops of rain. The rain must be on the side away from the observer. The position of the rainbow depends on the height of the sun, and raindrops at different definite elevations can produce the effect, so that double or triple rainbows are possible.

**VEGETABLE LIFE AND TEMPERATURE.**—It appears from observations made in France that the development of vegetable life is retarded by an average of nearly four days for each additional 100 yards of altitude. The arrival of the chimney swallow is delayed about two days for each increase of 100 yards in height.

**ELECTRICITY FOR LIGHTHOUSES.**—The British experiments to test the relative merits of oil, gas and electricity for lighthouse illumination have resulted in demonstrating the superiority of electricity over all other lights, even, as has been generally doubted, in dense fogs.

The velocity of light is so tremendous that it moves round the earth's surface, a distance of nearly 25,000 miles, in one-eighth part of a second.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

**STOP COCK.**—Wm. Swabel, S. F. No. 343,283. Dated June 8, 1886. This invention consists in a novel expanding-plug for stop-cocks, and in the means by which the plug is expanded. The object of the invention is to provide a stop-cock in which the plug can be tightly adjusted to its seat and relieved when desired.

**CARTRIDGE-LOADING MACHINE.**—Geo. J. Foster, Alameda. No. 343,706. Dated June 15, 1886. This invention relates to a machine for loading cartridges, and it consists of a novel arrangement and mechanism whereby the work is carried out. There are too many motions and details of construction to describe intelligently without the aid of engravings.

**SPRING HARROWS.**—L. A. Manchester, Merced. No. 343,717. Dated June 15, 1886. This invention consists in the combination of the peculiar curved spring-bars, the securing or uniting bands, and the teeth acting as wedges and tightening all the parts together. The object of the invention is to provide a single strong and effective harrow, the frame of which is of a springy character, the whole being secured together without bolts, screws or rivets, and having no separate cross-bars.

**FEED MECHANISM FOR DRILLS.**—Martin Schwarzler, S. F. No. 343,734. Dated June 15, 1886. This is an improved feed motion for drills, such as are used in factories, machine-shops, agricultural works, or for purposes where an upright drill is used. It consists in a bracket secured upon a drill frame, and having mounted on it a ratchet-wheel, which is actuated by a pawl operated by a cam on the driving shaft of the machine, a vertically-moving rack-bar, to the lower end of which the drill spindle is coupled, and gearing, by which the power of the ratchet is transmitted to the rack-bar. It consists, further, in details of construction relating to the means for coupling and uncoupling the ratchet-wheel from the shaft, the means for guiding, limiting and raising rapidly the rack-bar to which the drill spindle is coupled, and a lever for regulating the work of the actuating pawl.

**SAW TOOTH.**—Simon Kinney, Brownville, Yuba Co., assignor of one-half to S. H. Pratt, same place. No. 343,713. Dated June 15, 1886. This bit or cutter to be used in circular saws consists of a curved bit having its front and rear grooved to fit corresponding tongues in the socket of the saw-plate into which it fits, the bit having a slot made longitudinally in it from the base outward, so that one side forms an elastic tongue. The base or inner portion of the bit is wider than the outer portion, and when introduced into the slot or channel in the saw-plate the elastic tongue allows it to be compressed until it reaches its final position, when an enlargement or catch at the lower end falls into a corresponding place in the socket of the saw-plate and locks it firmly. By the peculiar construction the inventor is enabled to place more bits in the saw-plate than by other means. The throat for the escape of sawdust is a natural one. The points of the bits are presented at a greater angle than by ordinary styles of construction, and thus provide an easy-cutting edge.

**NATURAL GAS.**—The following from the Oil City, Pa., *Derrick*, was recently reprinted in the *Fresno Examiner*: "Messrs. E. J. Beane and J. R. White, officers of the Standard Gaslight and Fuel Company, of Merced, California, are in this city for the purpose of procuring outfits to drill a number of oil and gas wells in the San Joaquin valley, California. The company represents a capital stock of \$10,000,000, made up of private capital on both sides of the Rockies. The company proposes to pipe gas from San Joaquin valley to San Francisco, a distance of 80 miles. The Standard Gaslight and Fuel Company located 150,000 acres in the counties of Stanislaus, San Joaquin, Merced, Fresno, Tulare and Kern. In the San Joaquin valley there are upward of 50 artesian wells, all of which produce more or less gas. Some of these have struck pockets of gas at 800 feet and less, with enough gas pressure to lift the tools out of the well. It is the purpose of the fuel company to drift 2000 or 3000 feet, if necessary, to find an ample supply of vapor. It will start four wells at once. Mr. Beane, who is general manager of the concern, wants to place himself in correspondence with some first-class drillers and contractors with a view to letting the work. He authorizes us to say that the best wages will be paid good men. At the same time he will satisfy whom it may concern that he means business. Contractors and drillers will do well to call on the gentleman or address Collins house, this city. The headquarters of the gaslight and fuel company are permanently located at Merced, California. A number of practical oil men, we understand, are mixed up more or less prominently in this concern."

**MASSACHUSETTS** land-owners are planting worn pastures with chestnuts, both for timber and nuts.

**ALASKA** is said to have in its forests, at the lowest estimate, 5,000,000,000 feet of lumber.

## USEFUL INFORMATION.

## Pine Leaf Carpets or Matting.

We have already made brief reference to the production of a new kind of carpeting or matting, and some other coarse goods, from pine leaves. The Charleston, S. C., *News and Courier* gives the following description of the process of this new and curious manufacture as carried on at Cronly, which is a village close to that city. It should be said that the fiber mill referred to prepares the pine leaves for use as a substitute for jute, cocoa or flax.

"The carpet mill, which is situated some distance from the fiber mill, is a large two-story structure which is, however, as yet in its infancy, as the company has but recently commenced the weaving of carpets and matting. The appliances and machinery are about the same as those in use in establishments of like nature, the machinery of course being adapted to the spinning and weaving of the new fiber. This is brought over from the fiber mill after being dried, and is first put through a carder and cleaner, all the impurities being removed, and after being carded emerges in the shape of slivers about three inches in width. The fiber now assumes the first appearance of yarn. These slivers are caught in cars and then go through a drawing frame where four slivers are converted into one. A second drawing frame converts two of these into one, the sliver growing smaller and more condensed all the time. Next it is taken to the roving frame, whence it emerges in the shape of coarse yarn and is wound upon spools. It next goes to the spinning frame and finally to the twister, where two, three or four strands are twisted into one. It is then ready for the loom. To make colored carpets the yarn is either dyed or bleached, the yarn being wound into hanks for the purpose.

"At present, the company is running but one loom, which was made for experiments. These have proved so satisfactory, however, that orders have already been given for 30 additional looms, while a contract has been made with a well-known New York house to handle all the products of the mills. The carpets are made up in rolls, and in various patterns. The natural color of the pine straw yarn is a rich dark brown, which when bleached becomes a creamy yellow. Stripes of blue, red, green and yellow are woven into the patterns. The matting is made to imitate the finer grades of cocoa so perfectly that were it not for the aromatic odor, which is one of the best qualities of the pine carpet, an expert would find it difficult to tell one from the other."

**SPRUCE** is fast taking the place of poplar and other woods for making paper pulp. When the first paper was made from wood pulp it was thought that poplar was the best and perhaps the only wood which could be used, but during the last few years it has been found that spruce wood made better and stronger pulp than poplar. It is claimed by some that spruce wood does not make so white pulp as poplar, and that the chemicals for bleaching are somewhat more expensive in the case of the spruce, but it is much sought for on account of the strength of its fiber and the better character of the wood. Lumbermen are quite ready to get out a certain percentage of spruce for the wood-pulp grinders, because they will take some seamy trees, where reasonably clear and of good growth. Such seamy trees are not profitable for sawing into any kind of lumber. There is a great difference in the color of spruce, that which is very white being much more desirable for the wood-pulp people. Trees of the same variety seem to differ in whiteness or color, probably owing to the soil upon which they grow. Hence some lots are really worth a dollar a cord more to manufacture into wood pulp than other lots, while both might be worth equal prices for manufacturing into ordinary lumber. The pulp business is destined to grow more rapidly in the future even than in the past, for the users of pulp and paper and cardboard are becoming multiplied every year. The inventive genius of the Yankee discovers many new applications for a product like this almost every day, and the time is rapidly drawing near when a large quantity of spruce and poplar will be required to meet the demands of wood-pulp grinders.

**THE TAR, ETC., YIELD OF DIFFERENT WOODS.** According to experiments by M. Senff, the yield of crude pyroligneous acid, tar, charcoal and gas is almost the same with the most different woods. But the richness of the acid waters in acetic acid, and consequently the yield of dehydrated acid, vary greatly. In this respect the wood of coniferous trees is the least valuable. The wood of the trunk furnishes more acid than that of the branches. The wood yields more acid than the bark, and sound wood more than dead wood. Rapid calcination yields more gas at the expense of the condensed products and of the charcoal; it yields also the weakest acid waters and the charcoal is more hygroscopic than that furnished by a gradual action.

**THE USE OF NATURAL GAS FUEL** has led to the manufacture of mirrors in Pittsburgh. Up to this time all mirrors manufactured in the United States have been from imported glass. The quality of the glass, to retain the silvering and give a perfect production of the object, must be of the best. This quality Pittsburgh had never been able to produce until natural gas

came into use. Now, by its aid, the fineness of the glass produced rivals that of the imported article. The entire absence of impurity, the perfect fusing of the ingredients, the rapidity of the melting, and the pure, intense flame for reheating or working, are the principal advantages.

**WOOD OIL AS AN ILLUMINANT.**—Wood oil is made on a large scale in Sweden from the refuse of timber cuttings and forest clearings, and from stumps and roots. Although it cannot well be burned in common lamps on account of the heavy proportions of carbon it contains, it furnishes a satisfactory light in lamps especially made for it, and in its natural state is the cheapest of all illuminating oils. Thirty factories produce about 40,000 liters of the oil daily. Turpentine, creosote, acetic acid, charcoal, coal tar oils and other useful substances, are also obtained from the same materials as is the wood oil.

**A BIG RAISE.**—A Chicago firm has undertaken to raise the Robinson house, in Pittsburgh, to a height of seven feet greater than it is now without in any way disturbing its inmates. The house has a frontage of 130 feet on Seventh street and 110 feet on Duquesne way, and is four stories high. The walls are of massive thickness, the foundation stones of great weight. The work of raising will require six weeks, and cost \$9000. The necessity of raising the house arose from the elevation of the street to get a proper roadway approach to a bridge.

**CREMATION BY GAS.**—The first cremation in Pittsburgh, and the first in the world where natural gas was the fuel used, occurred last month. The furnace attained a heat of 2500° F. before the body was placed in it. In one hour and 30 minutes the body, weighing 160 pounds, had been reduced to lumps weighing six pounds. A draft of air admitted to the gas flame assisted in developing a greater degree of heat. No odor was observed and no smoke arose from the stack.

**BEAT YOUR CARPETS OFTEN.**—The oftener carpets are shaken the longer they wear. The dirt that collects under them grinds out the threads. Do not sweep carpets oftener than is necessary. A broom wears them very much. When a carpet is faded, strong salt and water will often restore the brightness of the color.

**HOW TO MAKE WAX INTO A LIQUID.**—Wax may be made into a liquid to be used in writing by dissolving it in alcohol, ether, or some essential oil. After written with, evaporation will leave the characters present in wax.

## GOOD HEALTH.

## Rabies and Yellow Fever.

M. Pasteur has just received a gift of 10,000 francs from Havre, to be employed in the furthering of his experiments in inoculation against hydrophobia. That scientific men claim that Pasteur's claim to prevent rabies has merit enough in it to invite a thorough investigation, is evidenced by the above and many other facts. Commissions are now being sent to Paris from different governments to examine into and study his method. The English government has appointed such a commission, consisting of some of the most eminent men in the kingdom. One of New York's most distinguished physicians has visited Pasteur, looked thoroughly into what he has done, studied his system, and is now putting up a hospital in New York to treat patients after that method. Germany, by the selection of Virchow and Koch, has shown her interest in the matter. The Academy of Medicine, of Rome, has sent delegates for the same purpose, while the Archduke Charles Theodore, of Bavaria, a physician, has started for Paris to make an investigation on his own account. It would seem from the above that some decided results may be reached from these investigations, and that the truth or falsity of his claim is in a fair way to be established beyond peradventure. All reports thus far have been highly favorable.

The latest published summary of his work is up to April 14th, up to which date he had inoculated 688 persons, presumably bitten by mad dogs, with only one death. He had also inoculated 19 Russians bitten by a mad wolf. Of these 19, 3 have died from hydrophobia—about 16 per cent. The usual per cent of deaths from the bites of mad wolves is said to be about 67. Since April 14th, Pasteur has treated other Russians bitten by mad wolves and mad dogs. One of the former recently died from the effects of his wounds; one of the latter from hydrophobia, after having been submitted to treatment. This makes in all 720 cases treated, with a total of five deaths from rabies, despite treatment. Pasteur has found that the rabies resulting from wolf bites is the same as that of dogs, and only more dangerous because the bites of wolves are more numerous and severe.

## Yellow Fever Prevented by a Similar Method.

Reports even more remarkable come from South America relative to a successful process of inoculation for yellow fever by a physician in Rio Janeiro, and a bill is now pending before Congress for the appointment of an American commission to visit that city and inquire into the merits of the claim. It is to be hoped

that Congress will not fail to pass the bill. It was introduced at the instance of Dr. Joseph Holt, of New Orleans, and has received the endorsement of the American Public Health Association. From the daily press we learn that the physicians of the military garrison at Vera Cruz have already commenced inoculations for the prevention of yellow fever. The material employed is injected hypodermically at intervals of eight days. Such a commission as could be selected from this country could establish the value of this method of prevention of yellow fever, so strongly advocated by Freire and Carmona.

The name of the physician who has introduced this practice is Domingos Freire, M. D., of Rio Janeiro. In a recent letter to Dr. Holt, above named, Dr. Freire says: I have performed over 7000 inoculations with full success; the immunity was almost absolute, notwithstanding the intensity of the epidemic this year. More than 3000 persons who were not inoculated, died of yellow fever; while among the 7000 inoculated, inhabiting the same infected localities, subjected to the same morbid condition, but seven or eight individuals, whose disease was diagnosed as yellow fever, died.

**THE EAST WIND.**—"Hang the east wind," said a physician in Boston to me one day; "it seems to drive all my delicate women patients wild." And what is there in the east wind that is so distressing? The *Lancet* says: That the east wind has, from the earliest time, been credited with evil influence, is apparent in the fact that Ephraim was described in one of the most ancient Jewish traditions as feeding upon it. What a repast! Modern science has determined that what we call the east wind is really a current of air from the north, its direction being modified by the rotatory movement of the earth. This is not difficult to understand. The avidity with which the dry cold wind from the north takes moisture, and particularly the secretion of the mucous membrane lining the air-passages, inspissating the mucus, and as it were, gluing together the cilia of the epithelium, is the real cause of its malignancy. We have repeatedly explained this fact, and pointed to the use of a succulent jujube, or something which will give off moisture in the mouth to be carried into the air passages with the inspired air, as the best of practical measures of protection. We believe that if only the habit of keeping a morsel that gives off aqueous vapor—not one that dissolves by taking up moisture—in the mouth during the time of exposure to the east wind were formed, there would be very few colds from that cause.

**SUNSTROKE OR THERMIC FEVER.**—As sunstroke, or thermic fever, is a very rare occurrence in this State, but does occasionally occur, a few words in regard to its treatment may not be amiss. Generally, the first symptoms observed are headache, ringing in the ears, rapid beating of the heart and vomiting; the skin ceases perspiring and unconsciousness quickly supervenes. The person so attacked should be at once laid down in the shade; all clothing but one thin garment removed; ice applied to the head and body, or where ice cannot be obtained cold water should be dashed on the body, or the person wrapped in a wet sheet and cold water applied. If he can swallow, and the pulse is weak and rapid, a little wine and water may be administered, or a little cold milk or beef tea, until a physician is summoned. Avoid giving whisky or brandy, as they are more apt to kill than to cure.—*Salinas Index.*

**POISON OAK.**—The *Contra Costa Gazette* of a recent date gives the following: A singular case of poisoning from poison oak occurred here during the early part of the week, the victim being Mr. A. P. Nelson. Mr. Nelson has been in contact with poison oak on numerous occasions while out hunting, but this is the first time that it ever affected him. It appears that a resident of Morgan Territory sent him a pair of boots to mend. The owner had evidently been walking through poison oak, for the boots not only poisoned Mr. Nelson's hands, but he also absorbed the poison into his face, which in a short time swelled to an enormous size. Remedies were applied and he has since recovered from the effect.

**THE VENOM OF A BEE** being acid, its effects may be neutralized by the application of an alkali, such as a very small quantity of liquor potassae. Another remedy generally at hand is a solution of tobacco; a pinch finely cut, should be laid in the hand and moistened, then worked with the thumb and finger till the liquid is quite dark colored. The entire mass should be applied; the finely-divided tobacco acts as though it were a sponge. As soon as the tobacco gets dry a little more may be added and the juice pressed out upon the inflamed spot for five or ten minutes. Road mud, wet, is good where nothing better can be readily obtained.

**SCARLET FEVER.**—Another case showing the communicability of contagious diseases by clothing is reported from Bath, Me., where a girl had scarlet fever at a boarding-school. After recovery she returned home, and a trunk containing the clothing she wore while sick was put away in the garret. Six months later two little girls were playing in the garret, and, opening the trunk, took out some of the clothing. In a week both were taken very ill with the disease and one died. There were no other persons ill with scarlet fever in the community,

## MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

## CALIFORNIA.

## Amador.

**THE NEW KENNEDY MILL.**—*Dispatch*, June 26: Grading was commenced for the contemplated 40-stamp quartz mill at the Kennedy mine last Wednesday, and a force of 30 or 40 men are employed thereon. Contracts for the iron works have been effected with a San Francisco firm, and it is understood that the mill is to be completed by the 1st of September.

**NEW MILL.**—*Amador Ledger*, June 26: We learn that grading has been commenced for a new 40-stamp mill for the Kennedy mine. It is not probable that this important step would have been taken unless the underground developments were of a decidedly satisfactory character. The Zeile mill was started again Thursday evening, after several days' idleness caused by repairing and cleaning out the reservoir.

**SUTTER CREEK.**—The Amador Consolidated mine was the scene of an accident last week, which may cause some delay in the regular prosecution of work. In hoisting water from the sump, the rope broke when the skip had reached a point about 100 feet from the water level. Only a short time previous to this mishap seven men had ascended to the top in the skip without accident. The skip and most of the wire cable is in the sump. E. Pritchard, the foreman, started for San Francisco the next morning to consult with the directors as to what shall be done in this emergency. In all probability a new rope will be sent up shortly, as the old one is badly worn, and has been spliced several times. The new air compressor is in running order, but has not worked very satisfactorily so far, owing to the inability of the nozzle to carry enough water to run the machine at the necessary speed. A new nozzle has been put in, and the compressor has been working in good shape ever since. The South Spring Hill Company has let a contract for building 10 additional stamps to its mill, which will give a capacity of 50 stamps. Knight & Co. have secured the job, and will commence work thereon immediately.

## Calaveras.

**SEARCHING FOR THE VEIN.**—*Calaveras Citizen*, June 24: Last week it was currently reported upon our streets that some exceedingly rich float quartz had been found on Indian creek by James Bean. The day following the discovery a corps of prospectors went down to the locality and began search for the vein. Their efforts were rewarded by finding one small lode carrying gold, but not in sufficient quantity to impress them that the object of their search had been found. More prospecting will soon be done in the vicinity. The parties are in hopes of finding the original vein that casts out the float ore, and if they do, they will undoubtedly report a discovery startling to the natives in its exceeding richness.

**INDIAN CREEK MINING.**—*Mt. Echo*, June 23: Indian Creek, as a mining center, is rapidly winning a reputation second to none in the State. Considerable activity prevails in this favored section at present, and judging from the recent valuable discoveries made, not only upon the new locations, but in the more developed mines that have been in constant operation for many past years, bids fair for a revival of the olden times when mining was the sole industry and dependence of the Calaveras laborer. The celebrated Wood mine is making a wonderfully brilliant showing. Stopping is being carried on vigorously in the eastern and western stopes, at the upper tunnel, where a ledge two feet in width of "ribbon-rock" immensely rich in galena and free gold is being mined. Rapid strides are now being made to place the mill in working order, and the transportation of the ore to the mill will be commenced at once. The Crothers mine, situated south of the Wood mine, is pushing ahead with considerable vim. The tunnel at present penetrates the hill 180 feet, where a well-defined ledge presents itself. Some very good deposits have been found in this mine. At the Bean mine developments are going steadily on. The tunnel, now 100 feet in length, will, it is expected, tap the main body of ore within 20 feet further. Some very good ore extracted from a shaft 40 feet in depth can be seen on the dump, and it is the intention of the company to tap this body of ore at a depth of about 200 feet. At the Calaveras mine everything is "booming." The mill is running daily and is receiving some of the richest rock extracted from this mine for a number of years. The Schillotte mine, owned by Louis Schillotte, is worked regularly and the tunnel now 100 feet in length is rapidly approaching the ore body in the shaft which it is intended to tap upon arriving at the point of destination. The vein, although quite narrow at the end of the tunnel, shows signs of an increase in width and prospects largely. In former days some very rich rock was taken from this mine. At the Kelley mine extensive preparations are being made both at the mine and upon the mill site. Part of the new mill to be erected has arrived upon the ground and the work of placing it in position will be commenced at once.

## Fresno.

**BONDED.**—*Tulare Times*, June 24: Dave Douglass, J. S. Johnson and Mark Lavelle, who went last week to inspect the newly-discovered mines at Temperance Flat, Fresno county, returned to Visalia Tuesday afternoon. They are well pleased with the outlook in that district and have bonded two mines, the Yellow Jacket and the Scorpion, and will begin work on them as soon as their tools can be moved there from Mineral King. Mr. Johnson has some fine specimens of gold quartz from the Yellow Jacket, a few tons of which would enable him and his partners to retire from the scenes of labor for a few years at least. The Georgia, another rich mine in that district, is being developed by Frank Hammack, of Fresno. The vein is 18 inches wide and the ore assays \$1000 to the ton. The gold mines of Fresno county are attracting considerable attention at this time.

## Inyo.

**MODOC.**—*Inyo Independent*, June 26: In the

Modoc mine, at Lookout, there is now a larger body of ore in sight than ever before. Mr. Fitzgerald is sending ore to the furnace and shipping to San Francisco at the same time. A large part of the ore is so high grade that it pays better to ship it than to smelt it at home.

**THE YGNACIO.**—*Register*, June 26: The dumps of this Cerro Gordo mine continue to turn out quantities of good milling ore. About 200 tons are now sorted out, making but very little impression on the unsorted piles.

**THE COLDWATER MILL.**—Mr. Melvin has sold his interest in this property, and left by Tuesday's train for Terre Haute, Indiana. The owners of the Casey mine are the purchasers. The mill will undergo some changes, and be set to work shortly.

## Kern.

**GREEN HORN DISTRICT.**—*Calico Print*: We have received some good-looking ore from a mine in Green Horn district, Kern county, owned by O. H. F. Hansen, situated about 40 miles from Bakersfield, on the county road. An assay from the croppings went \$310 per ton in gold and silver, but the rock has improved since sinking was begun, the shaft being down 12 feet, from the bottom of which the ore that we received was taken. The ledge is from 14 to 16 inches wide and in granite formation. The ore improves as depth progresses. There is an abundance of wood and water about the mine, and plenty of feed for stock. This mining prospect would be a paying proposition to parties with sufficient capital. The ore is free milling and it can be mined at a nominal expense.

## Mariposa.

**BUILT A MILL HIMSELF.**—*Mariposa Gazette-Herald*, June 24: George Chittenden has, after a siege of hard work, all by himself completed his five-stamp, water-power quartz mill on Bear creek. We learn from one who has visited the spot that it is about as perfect a job of the kind as ever has been done in the county. The mill commenced crushing ore last Monday. Chittenden for his industry and genius ought to succeed, and we think he will. He has had a long experience in mining.

**GOOD ENOUGH.**—M. M. Rumley, the lucky miner, appeared in town on Thursday evening of last week from his mine. He brought in some \$800 or \$900, the product of his labor since his last visit here, about a month or six weeks ago. All the machinery he uses at his mine is a pick, shovel and pan, driven by self-motive power. This is about \$10,000 he has taken out since he discovered the mine, some time last winter. Upon being asked if there was any more left, he said, "Yes, bushels of it. It sort o' looks that way."

## Nevada.

**THE CROWN POINT MINE.**—*Grass Valley Union*, June 25: Last week some very rich rock was taken from the 180 level of the Crown Point mine, and the ore now being extracted is of a high grade. The ledge in the 180 level is about six feet in width, with smooth walls. An air and escape shaft has just been completed from this level to the surface, giving good ventilation to the mine, and insuring the miners a way of escape in case of an accident. The work of drifting on the 300 level is going on, and a contract has been let to extend the drift a distance of 100 feet or more. On this level the ledge is full 11 feet in width, all good milling ore, and it is expected that the rich pay chute will be struck in the course of two or three weeks. Several improvements are contemplated and will be made in a short time if the mine is not sold, among which will be the putting up of a 20-foot Pelton wheel, and an addition of ten more stamps. The new wheel will be used exclusively for running the stamps. The pump handles the water in the mine very easily, and in fact has to be run quite slowly, as the water is "in fork" most of the time. The Crown Point is destined to be one of the best mining properties in the State.

## Plumas.

**GRANITE BASIN.**—*Cor. Plumas National*, June 26: Mr. J. A. Hall is running his mine and mill to their full capacity. He has made arrangements to buy the Jenny Lind mine and has hired ten Chinamen to go to work immediately. Mr. Rockefeller and company are running the mill night and day on rock from the Granite mine, which shows up well on the plates, showing it is a good investment to the owner. See & Jolly are driving their tunnel on the Specimen mine with great vim, in fair-milling ore. Swan & Frethy have finished their quartz contract on the Siebert mine, and Mr. Frethy intends to start for his home in Trinity county in a few days. Mr. Swan has sold his engine to Mr. Stampfli, of Indian valley. He will replace the engine with an overshot water-wheel, which will greatly reduce the cost of crushing his quartz.

## San Luis Obispo.

**GOLD MINES.**—*San Luis Obispo Tribune*, June 20: Mr. Horace Pullen, locally known as "Lord Pullen," is engaged with Charles Spurgeon in mining for gold on Navajo creek, on the eastern slope of the San Jose range, in this county. The mines of Navajo are among those commonly known as the La Panza mines, gold being found in greater or less quantities throughout the range, some 20 miles in extent. The locality where Pullen, Spurgeon and others are working is about five miles north of the La Panza postoffice. Mr. Pullen brought to the *Tribune* office several packages of gold-dust, aggregating about \$100, which he had washed out of his mines. The method of washing is by shoveling the dirt into sluices. Water is obtained from Navajo creek, where a dam makes a small reservoir, accumulating water in four or five hours to give a wash of three-quarters of an hour, and by such work the miners make about \$5 a day to the hand. Mr. Pullen and his partner will now prepare for the winter by running a bedrock channel in which to lay a flume. They have sunk a shaft 12 feet deep in the upper part of their claim, which is 3000 feet long by 400 feet wide, and find five feet of dirt that prospects four cents to the pan, and the color can generally be found in top dirt. By hydraulicking this Pullen is confident he can make over \$100 a day. There are now 30 or 40 men mining in that region, and all feel elated over the prospects. He says there is a party of Englishmen and a Spaniard mining above him who have taken out quite a large amount of gold.

## Santa Cruz.

**COAL.**—*Santa Cruz Sentinel*, June 24: Mrs. Reigart, who lives near Corralitos, brought into town

recently specimens of a coal formation found on her ranch. It is something like the Lincoln coal, being in the first stages of coal formation, and is strongly charged with gas. When ignited it gives out a strong flow of gas.

## Shasta.

**MILL RUNNING.**—*Shasta Co. Democrat*, June 24: Andy Fife keeps his Huntington mill on Spring creek constantly running on custom ore. Billy Groves of this place, and his partner Banks, are working a fine prospect on Dog creek. We are informed that the Iron Mountain Mining Co. has sold its eight concentrators. Jack Conant has the plans and specifications of his ten-stamp quartz mill in hand, and is making preparations to put the mill up. All the machinery will be driven by water power. DeForest, Reid and Hi. Bemis are prospecting a mine at Lower Springs on widow Myers' place, and are taking out some rich ore which they are working in DeForest's arastra. Oliver Sunderhaus, of the mining company, Sunderhaus, Busch & Co., who lately purchased several mines on Squaw creek, returned from Frisco Sunday evening. He is superintending the purchases and making things lively in that camp. It was reported in a Red Bluff paper that the Cressus mine on Squaw creek was sold for \$100,000. We are reliably informed that that is an error. The price paid for the mine was much less. The Texas and Georgia Mining Company's mill in the Old Diggings was completely destroyed by fire last Saturday night. The fire is supposed to have originated in the roof by sparks from the smoke-stack. This was one of the finest five-stamp quartz mills in the county, the whole plant, buildings, etc., costing about \$10,000. We are informed that the company have already set about to rebuild, and put up a new mill. R. T. Taylor and A. Alexander recently discovered a small vein of rich quartz on Squaw creek south of Rieley & Mathews' mines. Alexander came to town and reported the find to his partner Taylor and appeared to be highly elated over the discovery. The next day he disappeared, and a few days after was heard of at Millville. He had become so excited over his find that he lost his reason. Officers took charge of him and placed him in charge of the sheriff at Shasta.

## Sierra.

**RICH STRIKE.**—*Mt. Messenger*, June 26: Last week R. Sutherland and Mr. Moon came up from San Francisco to visit the quartz mine at Poker Flat, of which the former is a heavy owner. Mr. Moon is an expert, and he desired to see for himself what the mine could do. During his stay some 8 or 10 tons of the rock, from the lower tunnel, was worked in a Huntington mill, and the return was \$950, estimating the gold to be worth \$18 per ounce. We saw a number of specimens of the quartz, and it was very rich, being fairly seamed with gold. The ledge is from 3 to 7 feet wide at the lowest point where it has been opened.

## Slakiyou.

**CLEANED UP.**—*Yreka Union*, June 26: Louis Scheld, who operated the Scheld & Pellet claim, one mile west of Yreka, this season, finished cleaning up last week and realized \$1563. The claim may now be considered fairly opened, and next season there is every reason to believe that \$5000 will be hydraulicked out of the main channel, which is known to be extremely rich.

**SCOTT BAR.**—The Scott Bar quartz discoveries are holding out well and are being rapidly developed. Locations still continue to be made in that rich district. Magoffey & Ingram have completed their over-shot wheel above Scott Bar, and will soon be able to start work in the gravel, where they expect to find good pay. We hope they will meet with success. The quartz claims still continue to pay well, especially that of Classen & Robinson's. Henry Tompkins' also gives promise of making the owner a bonanza king. Henry Preckel is still working on Hooper hill. He has made a very good run this year.

## Trinity.

**TUNNEL.**—*Trinity Journal*, June 26: Sheridan Bros., of Junction City, are engaged in running a bedrock tunnel of 463 feet for a new opening to their mine on Simpson gulch. They expect to complete the job and be ready for sluicing before water comes again.

## Yuba.

**BONANZA AT SMARTSVILLE.**—*Marysville Appeal*, June 26: About 18 months ago James Landis and Merwin Loveridge, of Trinity county, went to Smartsville to prospect for quartz, during which time they have worked steadily to uncover a bonanza, and have sunk on the ledge 125 feet. Quartz experts pronounce it a very fine ledge. It is learned that several tons of the rock milled \$7 per ton gold, the sulphurets going \$63. When it is considered that the rock can be milled for \$1.50 per ton it must appear that there are indications that this great quartz belt will be shown up and that Yuba, at no distant day, will stand in the front as a quartz-mining county. With that class of mining the prosperity of the neighboring town of Smartsville is assured, and will add materially to the wealth of the entire county.

## NEVADA.

## Washoe District.

**CHOLLAR.**—*Enterprise*, June 26: The station for the 3200 level is being cut out on the west side of the Combination shaft, and it has already attained a westward distance of three sets of timbers or a dozen or 15 feet. The ground works admirably, and even better progress will be made as adequate distance out of the way from the shaft is attained. As soon as feasible, some time next week, a lateral drift north will be started to meet and connect with the main lateral drift coming south from the bottom of the Hale and Norcross deep winze on the 3200 level—only about 150 feet or less intervening. This station is being cut out directly in the eastern portion of the regular vein or channel, and the material being of as promising vein matter as ever was found in the Comstock—quartz, porphyry and clay, with even a little ore—it is not at all impossible to cut into a paying ore body directly from this shaft station.

**HALE AND NORCROSS.**—The lateral drift south on the 3200 level from the bottom of the deep winze is steadily progressing as fast as circumstances will allow, and there remains less than 140 feet to drift in order to connect with the 3200 station of the

Combination shaft. The diamond drill from the face of the north lateral drift on the 2900 level penetrated a distance of about 100 feet, reaching into the Savage ground. It passed through low-grade ore, and drew out an amount of sulphurets which seems to justify the belief that a paying body of ore will be cut into in advancing the drift. The drill has been withdrawn, and the water met with is being allowed to drain out. The drift will be advanced some time next week.

**SAVAGE.**—Work in the face of the lateral drift south on the 600 level has been suspended during the week, owing to the swelling nature of the ground, causing the timbering to crush in badly, necessitating much retimbering and easing of the lagging. The east crosscut has passed through several more good little stringers of ore, which show best to the southward, and another crosscut in that direction is very liable to find a good concentration of those veins in the ore body to which they evidently belong. Good ore is also liable to be found at the south end of the mine on the 2900 level from Hale and Norcross, as can be seen by reference to the Norcross portion of this summary.

**POTOSI.**—The diamond drill started a few days ago, about 200 feet back north from the face of the main south lateral drift on the 3000 level, to explore the heavy ore vein known to lie along the east side of the drift, has penetrated a distance of 150 feet, over 150 feet of it being in solid quartz without reaching the east side of the vein. It all assays a little, but gives no rich returns from this drill hole. Such an immense body of quartz calls for a bonanza. It was just such a huge vein or body of quartz that led to and held the great Crown Point bonanza, and a similar one led to and revealed the still greater bonanza in Consolidated Virginia and California.

**CROWN POINT AND BELCHER.**—About 60 men are employed extracting ore and at development work, using the single hoist engine at the shaft. Owing to the heavy shaft of the main hoisting engine being found to be badly sprung, necessitating its having to be taken to the foundry for strengthening, etc., work with the full mining force has to be deferred until next week, and perhaps until the first of the month.

**CON. CALIFORNIA AND VIRGINIA.**—The usual abundant supply of low-grade ore—about 400 tons per day—continues to come from this seemingly inexhaustible mine, but the average value, according to the mill battery samples, is less than \$10 per ton. Improvement in quality is desirable to stave off assessments. On the 1400 and 1600 levels the exploration drifts northwest and southwest are making good, steady advancement.

**GOULD AND CURRY.**—The next crosscut from the upraise incline, 50 feet above the 500 level, is now in 84 feet in vein matter which gives low assays. The east crosscut at this same point is in 45 feet—same material. A north lateral drift has been started from the west crosscut above mentioned, which is in 22 feet; material, principally porphyry and clay, with little quartz.

**OPHIR.**—The west crosscut on the 300 level is making good progress. On the 1300 level a station has been opened from the shaft and a drift west started therefrom. The repairs and overhauling of the surface machinery are about completed, and the works will be started into operation again to-morrow or next day.

**ALTA.**—Connection is established with the old Lady Washington shaft on the 700 level, giving a splendid and much-needed circulation of air. The drift is now being straightened up and timbered where found necessary, and crosscutting west will be commenced shortly.

**SIERRA NEVADA.**—On the 520 level the north lateral drift from crosscut No. 2 was advanced 41 feet, making a total length of 170 feet. Material, vein porphyry and quartz; no water.

**BEST AND BELCHER.**—Only six feet more water remains to be pumped out in order to reach the track floor of the 2319 or bottom level. Superintendent Lyman expects to have the water all out by the 4th of July, raise the flag and fire a gun.

**MONTE CRISTO.**—The west drift on the 150 level from the shaft is evidently getting into the old vein formation, as the material is becoming much softer.

**YELLOW JACKET.**—Daily yield 140 tons from the old stopes and breasts above the 1500 level. No new features of development to report.

**KENTUCK.**—Daily yield 60 tons from the old upper workings, keeping the Rock Point mill steadily supplied.

## Columbus District.

**HOLMES.**—*Candelaria True Picture*, June 26: In the raise that is now up to a level with the 10th we have a fine body of ore. It is the best development so far as we have run in it that we have ever had in the mine. It is a foot-wall ore body and looks like the old chloride bodies that were taken from the hill. About 600 feet west of this last-mentioned ore body, on the 11th level, we also have a good prospect. We have run on this ledge about 25 feet and it looks well. The ore is good milling. The sulphuret winze looks well, but is not as large as it has been. The ore from this stope is high grade. The hot stope is not quite as large, but the ore that comes from it is high grade. The stope 60 feet east of last turntable, first shaft level, is looking well. We have taken a large amount of ore from this stope and it still looks and produces well. It is in the same ore channel as the raise above the 11th, 9th and 8th level ore bodies. They are all east of all work done by the Belle Company and in new ground. We have great confidence in this section of the mine. The stope 50 feet below first shaft level, and directly under the last-mentioned ore body, is still producing well. Sixty feet west of Cross development we have a good stope of ore. The Creer looks well. Mill No. 1 is running half time on Mount Diablo ore. Mill No. 2 is running half time on Holmes ore. We ship by this day's express six bars of bullion, assaying \$8688.

**MOUNT DIABLO.**—The south crosscut in the intermediate between the second and third levels has advanced 10 feet during the week. The intermediate between the third and fourth levels, near the No. 2 winze, shows two feet of \$80 ore. The east stope on the second level is giving some ore of good grade. We are getting a small amount of ore of high grade from between the first and second levels, near the bonanza winze. The stopes on the first level show no change. Bullion shipment, \$8786.43.

**Hawthorne District.**

**GOOD YIELD.**—*Inyo Independent*, June 26: Fifty-four tons of ore from the Lapanta mine, near Hawthorne, recently worked at the Cat Creek mill, yielded \$4000, or a little more than \$74 per ton.

**Jackson District.**

**STRUCK IT RICH.**—*Silver State*, June 26: Charley Wright reports that they have struck very rich ore in the Pennsylvania mine in Jackson district. The ore body was cut in the lower tunnel, where it intersects the vein. This has given the mine a decided boom, and encouraged everybody who has claims in the district.

**Mt. Hope District.**

**A PROMISING DISTRICT.**—*Eureka Sentinel*, June 15: A party consisting of Messrs. H. Donnelly, superintendent of the Eureka Con. mine; S. J. Beebe, superintendent of the Silver Conno; John McAulay, superintendent of the Bowman; B. Gilman, superintendent of the E. & P. railroad; District Attorney Cheney, Sheriff Stinson, J. P. Dunkle, Paul Roux, Lew Dunkle and a reporter of the *Sentinel*, went down to Mt. Hope yesterday on a special train to visit and inspect the several mining properties there belonging to Hon. Thomas Wren. The camp is distant some 24 miles from Eureka, and the run was made in 48 minutes, no count being made for the time consumed in taking on water at one of the stations. Upon the arrival of the party at the mines every one was surprised at the great showing of mineral. Mr. Wren took pleasure in pointing out to the party, first, the development work he had accomplished during the past two months with his force of ten miners, and the showing of mineral he had been able to make. After sinking an 8x5½-foot shaft from a tunnel to a depth of 60 feet, and cutting through several good prospects, he decided to run a drift and cut the ledge at that depth. There is no telling how large the ledge is, but it is highly probable it is over 200 feet wide. As far as cut and developed there is no portion of it but what is mineral-bearing. That near the surface assays from \$6 to \$10 a ton on an average. As depth is attained the assays increase, until now quite a lot of \$30 ore is in sight. Assays running as high as \$1500 to the ton have been obtained. The mining men of the party manifested considerable astonishment at the showing, and a couple of them predicted that when operations reached a depth where the ore was not so leached it would be found not only very rich but in large quantities. Superintendent Donnelly was especially pleased with the showing, and evinced no little interest in the several characters of ores of the district.

**Railroad District.**

**BULLION.**—*Elko Free Press*, June 23: At one time in years gone by, there were other camps in the district, but now Bullion and Highland are the only ones left. The former is well supplied with water from numerous springs, and several pretty gardens are to be found in the town. The furnace belonging to the Blue Bell Copper Mining Company is now closed down on account of the low price of copper, but there is some talk of its being leased by one of the other mining companies and started up on lead and silver ores. A few hundred dollars would put it in good shape for work. The Reilly furnace is being put in shape to begin work about the 24th of this month. Some 400 tons of ore are now piled in the ore-house ready for reduction. This is being added to daily at the rate of 25 tons. By the time of starting there will be between 500 and 600 tons of ore at the furnace. It is of 40-ton capacity, and is now in splendid order for working the ore to a high percentage. There are in the district something like 100 claims, many of which have been worked for several years past. Probably 20 of these are now being worked. Of course the majority of these claims are not opened out to any extent; still they have been operated enough to give an idea of their worth. The A. & A. mine, recently purchased from Charley White by Messrs. Ainley & Adams, has a tunnel 400 feet long penetrating it. The first chimney of ore was struck 235 feet from the mouth of the tunnel. Here an upraise leads to the upper tunnel 100 feet above. At the tunnel level this chimney of ore measures 8x16 feet, and at the upper tunnel 5x7—all carbonate. A shaft 250 feet from entrance of main tunnel is now down 70 feet, all in ore. This will be sunk 100 feet and a level started. The richest ore in the mine comes from this shaft. Fourteen samples, taken from different parts of the mine, averaged 40 ounces in silver and 25 ounces in lead. There is a large quantity of high-grade ore in sight—sufficient to keep a smelter running steadily for some time. Last year the output from the Standing Elk mine was close on to \$100,000, and from all appearances it is going to do better by \$50,000 this year. There are 28 men on the payroll of the mine, and by the first of the month it will be increased to 40, including the hands at the furnace. Considerable work has been done on the Tripola property, and extensive and rich bodies of ore uncovered. In fact, the ore from this mine is said to be the richest in the camp, assays going as high as 692 ounces in silver—saying nothing about the lead intermixed with the other metal.

**COLORADO.**

**THE SMELTER.**—*Elk Mt. Pilot*, June 26: The Tomichi Valley smelter, in Gunnison, the construction of which has been eagerly watched by our miners, fired up last Monday. The furnace runs successfully and everything works like a charm, as was expected from the practical manner in which it was built. The smelter has two furnaces, but only one was completed to start last Monday, which has a capacity of 50 tons of ore per day. The first 24 hours about 40 tons of ore was run, from which 192 bars of bullion was taken, which will assay 318 ounces in silver and 60 dollars in gold. The slag from this bullion contained very little or no mineral. Thus we might say that the smelter is practically a success, and at present have over 1200 tons of ore on hand with plenty more in transit. Surely we can see a brighter day dawning for the entire Gunnison country. The Domingo mine is turning out to be one of the best in Dark Canyon. It has been worked all winter under a lease by James Welton and others, and the boys have driven a tunnel 270 feet long, also a raise on the vein 60 feet long, sunk 30 feet of a shaft and drifted from the bottom of the shaft 65 feet, altogether making about 430 feet of rock removed, which we consider a very good winter's work. They have about 70 tons of ore to ship, 20 of which has already been shipped to the Gunnison sampler, and

the balance will be as soon as it can be packed out by jacks. The ore will probably average \$250 to the ton, which is far above the average of most mines. The ore is native and brittle silver, gray copper and sulphurets, and the rich streak is from one to two feet wide. A contract has been let on the claim in Redwell Basin, owned by Al Jacobs and J. H. Curtis, to Vic Anderson and Hugh Burns, to run a tunnel 50 feet for a half interest. Two carloads of ore was shipped from the Domingo mine to the Gunnison sampler this week.

**IDAHO.**

**THE BADGER CLAIM.**—*Coeur d'Alene Record*, June 14: Through the kindness of W. A. Parker, who has been superintending the work on the Badger claim, which has just shut down for want of water, we can give a few facts of general interest. At a cost of about \$1850, some \$600 of which would have contributed to future operations if work had been kept up, gold to the value of \$7698.60 was taken out. This is a profit or net value of a full \$1000 per week. A strip of 144 feet wide of the channel wash is stripped, and evidences are pretty clearly established that the entire width of the channel is about 250 feet. The depth to bedrock is now 35 feet. We frequently hear the theory advanced that this is an exceptionally rich claim, but Mr. Parker has made several tests, and for nearly three years has studiously observed all the developments which have been made along this channel for a distance of nine miles, and he unhesitatingly expresses the opinion that it is not likely that there is a marked variation in the quantity of gold along the entire line. The width and depth of the channel will vary, and the distribution of gold will vary accordingly, and so will the cost of working. Mr. Parker is supported in his opinion by nearly, if not every, practical experienced miner who has taken pains to study the subject carefully. We have no doubt that as a mining proposition it is reasonably safe to invest money upon this actual knowledge and theoretical conclusions. Tommy Davis showed us this evening the products of a small cleanup from the Tip Top claim, in which he is an owner. It was very fine gold and valued at about \$100. Work has been resumed on several of the principal placer claims in Prichard gulch since the water got low. The owners of the Mother lode have commenced excavating and getting out timber for an arastra.

**FROM THE GOLD BELT.**—*Wood River Times*, June 19: Our townsmen, S. J. Friedman and B. Schwartz, are owners of the Laura Benson mine in the Gold Belt district. They recently purchased it for \$4500, and at once set a force of men at work developing it in real earnest. The result is so perfectly satisfactory that these gentlemen will probably at an early day put in a mill to realize the "shining stuff" at once.

**PIONEER.**—*Idaho World*, June 9: M. Nelson, who has been at work in the Pioneer mine at Quartzburg and owned by the Gold Hill Company, informs us that the ledge is 30 feet wide—all pay ore. The Gold Hill Company began work on this mine, at the surface, less than a year ago. This mine is good at the depth of 400 feet. It was tapped with a crosscut run from the 400-foot level of the Gold Hill, and the amount of ore between where work is now carried on and that depth must be immense. There is no doubt that the Pioneer will turn out a far greater amount of gold than did the Gold Hill when it is worked to the same depth. The Gold Hill has yielded millions. The company now employs 21 or 22 men in the mill and mine.

**FROM BIG CREEK.**—*Coeur d'Alene Record*, June 20: B. Presley and E. G. Pond came in from Big creek yesterday. They had been prospecting in that vicinity the last five weeks, spending most of the time on the upper right hand fork which empties into the main creek about three miles up from the south fork of the Coeur d'Alene. They have been following up the mountain as fast as the snow disappeared, which is not yet all gone; have located several veins showing galena, which they will develop as fast as their means will permit. They report new finds along Big creek, especially in the upper region. Not a great amount of active mining is going on, but a slow, persistent progress is maintained which finds abundant encouragement. Wherever surface indications have been fair the prospect has not failed to improve as work has progressed. They venture the opinion that the Big creek mines will very soon command as much attention as those around Wardner.

**MONTANA.**

**THE ELKHORN.**—This famous property is now one of the most completely equipped in the Territory, though, of course, on not so large a scale as many others. It has a new hoist capable of working to a depth of 2000 feet, the power being supplied by two engines of 12x16 cylinders. Three 50-horse power boilers furnish steam for the pumps and for the Ingersoll drills that are now used throughout the mine. The shaft is now at a depth of 670 feet and is going down at the rate of three feet per day toward the 750, where a station will be cut and a level run. The lowest level is now at 650 feet. The ore is now being mostly taken out of the upper levels. The vein is from 6 to 16 feet wide in all the levels. The 15-stamp mill is now handling about 19 tons per day of ore that samples 54 ounces of silver. The daily saving is about \$950, or over \$25,000 per month. For months past regular dividends of \$5000 have been paid every 15 days—\$10,000 per month. The net profit in working the mine is about \$12,500, the balance over the dividends being applied to the improvement fund. The company now has five additional stamps on the way which will increase the output of the mine fully 25 per cent. The new plant will be in position about August 1st. C. L. Vawter is manager of the Elkhorn, one of the best conducted and equipped as well as one of the most profitable properties in the Territory.

**NOTES.**—Mr. F. M. Chadbourne came in yesterday from a trip to Marysville and through the Stemple district, with which he is much pleased. About 15 men are at work on the Jay Gould mine. The mine shows a vein of ore 7 feet wide and the owners are much encouraged with their prospects. The Homestake stamps are steadily dropping on rich ore. The vein is very narrow, but the ore is very rich and it is one of the best little mines in the Territory. The vein is traceable a distance of about three miles, though so narrow, and it is regarded as one of the curiosities in mining. Great numbers of very prom-

ising prospects are being developed in the Stemple district—a wide stretch of country—and prospectors are rushing in there this summer in a crowd. The directors of the James R. Keene mine have given authority to the manager to run levels on the vein until further notice. It is probable that within a few weeks a decision will be reached to immediately begin the erection of reduction plant. The mine is now developed by a tunnel of nearly 300 feet and a shaft of about 80 feet, and work will proceed very rapidly. Ore is being taken out worth over \$300 per ton. The Empire company have their assaying outfit on the ground, and in the future will carefully assort all ore that is mined.

**NEW MEXICO.**

**PYRAMID.**—*Cor. Clifton Courier*, June 19: At Pyramid, times have livened somewhat, and the usual sleepy appearance of the camp is gradually giving way to one of activity. The machinery for the Gypsy Queen mill is all on the ground, and the erection of the mill is now under way. The mill will be in running order probably about the middle of July. A small force of men are employed on the mines, and no additional hands will be put on until the mill is completed. The Gypsy Queen is the leading mine in the camp, and is attracting considerable attention. The mine is in shape to produce ore in unlimited quantities. At the 150-foot level ore was first found in quantity, which gradually increased until the 180-foot level was reached, where the vein is 21 feet between the walls. Five feet of this is high grade, while the entire ledge will average \$40 per ton. Four separate veins exist, which are uncovered by as many different drifts. The supply of ore need only be limited by the demand. An air compressor is among the improvements contemplated, and steam drills will be introduced. The mill is a ten-stamp with a capacity for increase. Duncan concentrators will be used, and gold as well as silver will be treated. The mill will also do custom work, which will prove a blessing to mine-owners in surrounding camps. The mines in the camp generally are looking well and the owners are confident of making a fortune.

**CONCENTRATING.**—*Socorro Bulletin*, June 25: The Eaton concentrator is running successfully in Magdalena district on Juanita ore. The Willis mine, of Silver City, is steadily shipping its rich carbonate ore to the Billing Works at the rate of 10 tons a day. Col. Donan is running a tunnel in the White Fawn, Pueblo district, and dumping the high-grade silver mineral, characteristic of this district. Graham and Stewart shipped a carload of their high-grade argentiferous copper to Denver on Wednesday from the Gutierrez mine in Pueblo district. Fluor spar in immense quantities exists within six miles of this city. The time is not distant when it will be anxiously sought after for fluxing purposes. The Iron King, in Gallinas district, continues to ship its iron flux to the Billing Works. The report that native silver has recently been found in this property is not confirmed. The main tunnel of the Grayhound is entering the mountain at the rate of four feet per day. The course of this working is in the direction of the Graphic mine, and the latter property will soon be exploited through this channel. The Eliza mine at 25 feet on incline No. 1 has an 18-inch streak of ore which upon determination is found to contain 38 per cent copper. The property is owned by the Oscura Mining Company, of New York, and is located in the Oscura district. The Brittenstine M. & M. Co., of Pueblo district, is shooting pay rock out of its Metzgar mine. It will next week open up in the Carnero. Its concentrating and milling plant blew out last week, owing to an insufficiency of teams to haul ore.

**OREGON.**

**ANOTHER MILL.**—*Sentinel*, June 26: C. K. Baeumle yesterday bought the quartz machinery owned by Messrs. Beekman and Klippel, and Mr. Klippel will go to San Francisco in a few days to get the balance of the machinery required to make it a first-class ten-stamp mill to be placed in position and ready for work in three months. The site selected for the mill is where the old Bauten mill formerly stood, Mr. Baeumle having purchased the ground and water right of Messrs. Curtis and Pape yesterday. He has an excellent prospect from his mines close by, and by the time the mill is running will have enough rock on the dump to run right along. Mr. B.'s father and brother will arrive in a few days and will assist in the management of the mill and mine.

**UTAH.**

**REVIEW.**—*Salt Lake Tribune*, June 28: The week has been sultry, the thermometer running up to 95 degrees at the Conservative signal station. The ores are coming down the canyons freely. No special mining event has marked the week. The shipments of ore and bullion out from this city during the week ending Saturday, June 19th, inclusive, were 1,643,544 lbs. The receipts of ore, as per the above of shipments, added to those held in the valley, are very large for the week. The ores received as per current reports for the week ending June 23d, inclusive, were valued at \$95,789.41; the bullion receipts were \$109,001.47, a total of \$204,790.88. The total receipts for the previous week were \$202,194.29, of which \$85,380.47 was ore and \$116,813.82 was bullion. The Ontario has sent down no bullion since the mill started after the cleanup. Ore sales for the week, two lots, \$16,166.83. No sales of Ontario stock are reported in New York for the week. The 121st Ontario dividend, of 50 cents a share, aggregating \$75,000, has been declared, payable in New York, making six regular monthly dividends aggregating \$450,000 this year, or \$3 per share. The Daly sent down during the week two shipments of bullion of seven bars each, valued at \$16,408.53; its ore sales were \$6364.90, a total output for the week of \$22,773.43. The base bullion receipts for the week were \$17,000; fine bars, \$16,400. The Hanauer smelter product for the week was \$33,390; the Germania, ten bars, \$21,130.25; the Pascoe, \$3800. The Stormont sent up on the 21st silver bars worth \$3270. The Alice sent in, on the 19th, 16 bars of bullion, \$14,011.21. Ore receipts were: By Wells, Fargo & Co. \$30,890; by McCornick & Co. (including \$8850 Crescent and \$3250 Queen of the Hills), \$50,430; by T. R. Jones & Co., \$14,469.41.

**List of U. S. Patents for Pacific Coast Inventors.**

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in Dewey & Co.'s Patent Office Library, 252 Market St., S. F.

FOR WEEK ENDING JUNE 22, 1886.

- 344,076.—ROCK DRILL—Brady & Fitzpatrick, Virginia City, Nev.
- 343,981.—CABLE RAILWAY—R. F. Bridewell, S. F.
- 344,243.—BUREAU—S. J. Bryant, Reno, Nev.
- 344,040.—ADVERTISING PUZZLE—L. O. Granger, S. F.
- 344,180.—ADDING MACHINE—Edward Halsey, San Jose, Cal.
- 344,181.—ARITHMETICAL APPARATUS—Edward Halsey, San Jose, Cal.
- 344,182.—TAX CALCULATOR—Edward Halsey, San Jose, Cal.
- 343,998.—BOILER TUBE CLEANER—W. H. Keep, Stockton, Cal.
- 344,051.—LINIMENT—J. W. Lauer, Mountain View, Cal.
- 344,121.—WATER LEVEL INDICATOR—W. S. Mayers, Ft. Apache, A. T.
- 344,129.—TWO-WHEELED VEHICLE—Newell & Litten, Fresno, Cal.
- 344,004.—QUARTZ BREAKER AND PULVERIZER—E. I. Nichols, S. F.
- 344,199.—DEVICE FOR TAPPING CANS—C. E. Quigley, Oakland, Cal.
- 344,215.—HOPPLE—J. T. Stoll, Sacramento, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

**Mining Share Market.**

Mining stocks have been rather stronger this week than for some time past. Although there is nothing very decisive in sight on the Comstock, the situation is regarded as rather promising. The diamond drill sent out to the eastward from the Potosi south lateral drift on the 3100 level has within the last week demonstrated the ore vein known to lie along that side of the drift to be over 150 feet wide, of pure, solid quartz, carrying more or less of the precious metals. This cannot even be classed up to low-grade ore in the line of practical milling operations, yet it is very suggestive of the fact that all good ore bonanzas on the Comstock lode have invariably been found in large accumulations or concentrations of quartz, which is the matrix, the gangue, the mother of the desired ore.

The 3200 station of the Combination shaft is being cut out in good style and the work progressing faster naturally the further it gets out of the way of the shaft. When it has reached an adequate distance west, the proposed lateral drift north will be started to meet and connect with the main lateral drift south coming from the deep winze of the Hale and Norcross. This drift connection is of greater importance than any other point in the mines of the Comstock to-day, as it will not only open up the new 3200 level at that point, but give excellent facilities for running into the lowest attained depths of the mines in either direction. The bottom of the shaft itself, at the perpendicular depth of 3250 feet, including the sump, is in as favorable a formation for gold or silver as was ever found or utilized in the Comstock section. The material is quartz, vein porphyry and clay, with occasional small spots and streaks of ore giving good assays, and although sinking deeper would be a very important proposition in the way of practically crosscutting and deeper prospecting the vein at the same time, it is deemed better at present to explore the 3200 level first.

**Bullion Shipments.**

We quote shipments since our last, and shall be pleased to receive further reports:

Moulton, June 23, \$24,000; Germania, 23, \$4,408; Hanauer, 23, \$8660; Pascoe, 23, \$1675; Germania, 24, \$8733; Hanauer, 24, \$5920; Queen of the Hills, 24, \$1270; Germania, 22, \$4357; Hanauer, 22, \$9260; Stormont, 24, \$3270; Queen of the Hills, 24, \$1550; Germania, 25, \$6645; Hanauer, 29, \$14,980; Stormont, 24, \$3224; Germania, 29, \$4248. For last week, Wells, Fargo & Co., of Salt Lake, received \$64,290; McCornick & Co., \$90,890; J. R. Jones & Co., \$35,599; and Union National Bank, \$14,011.

**Our Agents.**

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

## ENGINES and BOILERS

FROM 2 TO 100 H. P., ALWAYS IN STOCK.

A Full Line of MILL SUPPLIES AND LUBRICATING OILS.

### IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the IMPROVED FORM OF HYDRAULIC GIANTS, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. R. Hoskin et als.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,  
39 to 51 Fremont St., San Francisco, Cal.

This cut represents our

### IMPROVED HYDRAULIC MACHINE.

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List.

Inventor and manufacturer of the celebrated Slot Cut and Slot Punched Screens. Mining Screens a Specialty, from 1 to 15 (fine).  
Orders Promptly Executed

## THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

Manufactured only by

For Sale by  
DUNHAM, CARRIGAN & CO., San Francisco, Cal. | JENKINS BROS. 71 John St. New York,

**ADAMANTINE**

**Shoes, Dies and Crusher Plates**

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been for the last ten years; we warrant them to out-wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break **AT THE SHANK**, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also **CHROME CAST STEEL** for Mining and General Use, of the finest quality.  
For further particulars, address

**CHROME STEEL WORKS,**

**H. D. MORRIS, Agent, 22 Fremont St., San Francisco.**

When ordering, a rough sketch, with full dimensions, is all that is necessary.

## Haywards Hotel.

We take pleasure in calling attention to this well and favorably known resort. It has been long established and popular. The locality is elevated and healthy, the surroundings pleasant in the midst of the fruit region of Alameda county. The table will be found supplied with the best in the market, and the proprietor intends to spare no pains in making his house a pleasant and popular home for tourists and pleasure-seekers. Further particulars will be seen in the advertisement in this paper. San Franciscans and Oaklanders find it a very convenient and delightful place to tarry.

## Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

BORAX—6 1/2% @ 7 1/2 c.
BAR SILVER—97 1/2% per oz.
COPPER LAKE—\$10.00 @ 10.12 1/2.
IRON—No. 1, \$17 @ 18.50; No. 2, \$15 @ 16.50.
LEAD—\$4.85 @ 4.95.
QUICKSILVER—43 @ 43 1/2 c per lb.

The following is the latest by mail from the "New York Metal Exchange Market Report":

COPPER—Quiet, but fairly steady; Lake offered at 9.95c. Transferable Notices (Lake) offered at 10.00; Transferable Notices (Chili Bars) offered at 10.40.

LEAD—Quiet at 4.85 @ 4.95c. Transferable Notices (Domestic) issued at 4.90.

SPELTER—Dull at 4.35 @ 4.50c. Transferable Notices (Domestic) issued at 4.50c.

TIN—Firm and active, closing at \$22.25 @ 22.70. Transferable Notices issued at \$22.45c.

TIN PLATE—Dull. Transferable Notices issued at \$4.30.

IRON CERTIFICATES—Dull at \$15 1/4 @ \$17. Transferable notices (June delivery) issued at \$16 1/4.

SILVER—New York, 98 1/2% per oz. London, 44 1/2%.

MAKER'S PRICES—At tidewater. 100 ton lots of listed irons (when brand is specified) range nominally about as follows: Lehigh, Grade No. 1, \$18 @ 18.50; No. 2, \$17.00 @ 17.50; Grey Forge, \$15.00 @ 16.00.

Hudson River, Grade No. 1, \$18 @ 18.50; No. 2, \$17.00 @ 17.50; Grey Forge, \$15.00 @ 16.00.

Southern, Grade No. 1, \$18.00 @ 18.50; No. 2, \$17 @ 17.50; Grey Forge, \$15 @ 16.

Prices generally ruling for metals not regularly dealt in on call at the N. Y. Exchange, covering extremes of buyers' and sellers' views. All prompt delivery.—Australian Tin, \$22.40 @ 22.80; Billiton Tin, \$22.65 @ 22.75; Banca Tin, \$22.75 @ 22.85; Baltimore Copper, \$9.75 @ 10.00; Orford Copper, \$9.75 @ 10.00; P. S. C. Copper, \$9.75 @ 10.10; Foreign Lead, \$4.95 @ 5.05; Foreign Spelter, \$4.70 @ 4.75.

## Practical Treatise on Hydraulic Mining

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' lugs, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For sale by DEWEY & Co., Publishers, 252 Market St., San Francisco.

## Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A post card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

UNCLE Sam has found it at last! A sure remedy for Torpid Liver, Sick Headache, Habitual Constipation, Chills and Fever, and all affections of the Kidneys and Liver. This is a New Compound, and one trial will convince you that it is the Cheapest and Best Remedy in the Market for Diseases of Kidneys, Liver and Stomach. If you want a pure vegetable compound, that is positively guaranteed to contain no mercury, go to your Druggist, and get a Bottle of the Arkansas Liver and Kidney Remedy. Price, \$1.00 per Bottle.

FOR SALE BY ALL DRUGGISTS.

## THE ROLLER ORE FEEDER

[Patented May 28, 1882.]

This is the best and cheapest Ore Feeder now in use.  
 It has fewer parts, requires less power, is simpler in  
 adjustment than any other. Feeds coarse ore or soft clay  
 alike uniformly, under one or all the stamps in a battery  
 as required.

In the Bunker Hill Mill it has run continuously for two  
 years, never having been out of order or costing a dollar  
 or repairs.

## HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold  
 in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co.  
 (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting  
 that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works,  
 Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded  
 to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quanti-  
 ties to suit purchasers.

 splendid opportunity for an enterprising mechanic.

Address A. B. C., care of this paper.

# \$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,  
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.**  
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco. As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement. The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them. Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for. N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street.

SAN FRANCISCO, CAL.

# \$1,000 CHALLENGE ACCEPTED, PRICE, FIVE HUNDRED AND FIFTY DOLLARS (\$550.00).

**THE  
"TRIUMPH" ORE CONCENTRATOR.**

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE, placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

JOSHUA HENDY MACHINE WORKS,

Nos. 39 to 51 Fremont St.,

San Francisco, Cal.

**PACIFIC  
IRON WORKS**

1850. 1885.  
**RANKIN, BRAYTON & CO.,**  
BUILDERS OF...  
**MINING MACHINERY.**

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

## WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, A MOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS for smelting of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

**WATER JACKET  
SMELTING  
FURNACES**

**THE DUNCAN  
CONCENTRATOR**

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES THE BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

**Baker's Mining Horse Power.**

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

**HOISTING  
WORKS.**

## Cost of Gold Mining in Brazil.

The St. John Del Rey is one of the oldest gold mines now being worked, and may be considered a representative Brazilian mine. It will be interesting to California gold miners to learn something of the expense of gold mining in that country, especially as they are reducing the loss in treatment. The mine is owned by an English company, and at a recent meeting of the directors in London the following facts were elicited:

The total monthly produce of gold at Morro Velho from the 13th day of April, 1885, to the 12th day of April, 1886, both days inclusive, was 27,902.6508 ozs. troy. The produce for the corresponding period of last year was 26,102.0234 ozs. troy; for the preceding year, 22,908.7441 ozs. troy; the net profit on the working of the Morro Velho mine for the year has been £17,238 14 s. 3d.; the transfer and other fees, £10 15s. 9d.; the amount of net profit brought from last year, £3496 5s. 8d.; total, £20,745 15s. 8d. The general expenses for the year amount to £2760 8s. 8d.; debenture interest, £4518 3s.; income tax on interest, £86 12s. 8d.; bad debts in Brazil, £237 6s. 9d.; interest on loans, £87 2s. 7d.; total, £7689 13s. 8d.; profit, £13,056 2s. The amount of debentures paid off in November and following months was £15,450. Reviewing the figures, the result may be stated shortly as: First, that there has been less mineral raised and treated, caused mainly from want of power in the underground engine. Arrangements are in progress for an entirely new system of hauling, to supersede hauling by this underground engine, by which it is hoped the output will be considerably increased. Secondly, that the quantity of sand amalgamated has been considerably increased by the completion in April of four additional amalgamating barrels. Thirdly, that the yield or recovery has improved this year as last to the extent, in the two years, of, practically, 1 oit. a ton. Fourthly, that the loss in treatment this year as compared with last has been reduced 5.35 per cent. The rainfall during the past rainy season has been the smallest on record, only 39½ inches having fallen, the usual average being 58 inches. It is feared this may be inconveniently felt during the dry season now entered on. The total produce of gold from the Cuiaba mine during the year has been 2809.3713 ozs. troy. The produce for the corresponding period of 1884-5 was 3043.2102 ozs. troy. The quantity of mineral quarried and stamped was 16,718 tons, yielding .1593 oz. troy per ton. The quantity quarried and stamped last year was 18,736 tons, yielding .1699 oz. troy per ton. The average assay of the mineral stamped was .3798 oz. troy per ton, as against .3995 oz. troy per ton last year. The recovery of 1.384 oits. per ton, from the mineral which averaged 3.295 oits. a ton, shows the unrecovered gold to have been 57.43 per cent against 57.43 per cent last year. The total cost at this mine for the year was 11, £591 14s. 2d., as against £12,068 last year. The gold on sale produced £10,136 18s. 10d., leaving the expenditure in excess of the receipts

at £1454 15s. 4d. From the figures it will be seen that the total expenditure, both working and capital, has only been 13s. 10d. per ton, which a yield of 1.7 oits. per ton would have covered, and from the second set of figures that the working expenditure was more than covered by the yield of 1.384 oits. per ton, an important fact, as showing how cheaply the mineral from this mine can be raised and milled.

DEBRIS QUESTION IN CONGRESS.—The Committee on Commerce of the Senate amended the

## A Refinery for Bullion.

The process used on the Comstock for refining coppery bullion produced by amalgamating tailings was first used at the Lyon mill at Dayton, Nevada, and has been adopted at the other tailings mills on the Comstock.

These mills treat two classes of tailings: "sand," or material which has passed previously through the pans of the ore mills, and "slimes," or the fine, clayey material which, coming from the battery, is too light to settle

## Foundry Notes.

Matters in relation to the strike at the Union Iron Works remain about in the same condition as last week. The works are of course short-handed, and are still advertising for men, but none of the departments are shut down. The federated trades have sent the men under its jurisdiction a notice that the necessity for pecuniary assistance is felt, and that the present is a critical time in the life of the iron unions. The apprentices who threatened to return to

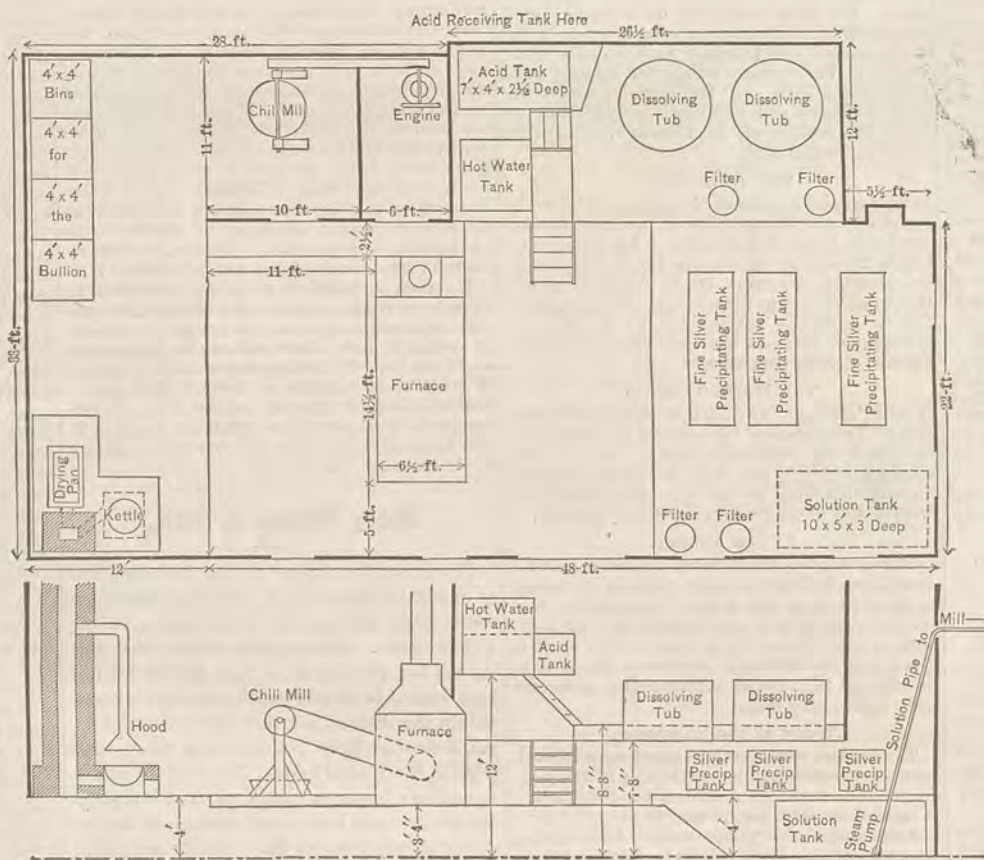

work unless they were recognized have received the assistance desired. The proprietors of the works, however, remain firm in their position, considering that the men had no reason to strike, as there had been no reduction of wages or increase of hours, and the men always received the highest prices for their labor and were promptly paid. They will not recognize any right of the unions to dictate to them what men shall be employed.

The Union Iron Works have just launched the third steel steamer built on this coast. She is a steel water boat for the Panama Railway Company, and will be towed down to Panama by one of the Pacific Mail Company's steamers. She is named the *Balboa*, and is 100 feet long, 14 feet beam, 8 feet depth of hold, and has three water compartments, with a capacity of 25,000 gallons. The engines are of the compound surface condensing type, the boilers being for 100 pounds of steam. The fresh water pumps aboard are capable of raising 10,000 gallons of water per hour. The house on deck, which extends nearly the whole length, is especially adapted for hot weather, and has ample accommodation for officers and crew.

The Fulton Iron Works have completed the machinery for the steam coasting schooner *Whitesboro*. The compound engine has an 11-inch high pressure and a 24-inch low pressure cylinder with 18-inch stroke. The works are also building a 40-stamp mill for the Kennedy mine, near Jackson, Amador county. The stamps weigh 850 pounds each, and the mill will be run by water power. Sixteen Frue concentrators will be used at the mill. The Fulton is still at work on the government dredges to be used in the bay and rivers, and which we have before described. They are working also on the double-ender ferryboat for San Diego bay, the dimensions of which we gave several weeks since. The engines for the new boat to replace the lost *Planter*, of the Inter-island Steam Navigation Company of the Sandwich Islands, are still in process of construction, making the fifth set made for this company.

There is still a lack of large contract work in the larger machine, foundry and boiler shops, and the dullness is reaching the smaller shops, even those which run on specialties.

NEW MINING DISTRICT.—The *Sierra Tribune* has received a letter from a friend who is prospecting in a new district on the border of Long valley, about four miles from Willow Ranch. The writer says they have a gold vein that assays from \$6 to \$30 a ton and is 8 feet wide,

ARRANGEMENT OF BASE BULLION REFINERY ON THE COMSTOCK.

River and Harbor bill by striking out the section directing the Secretary of War to bring suit to enjoin the hydraulic miners from washing mining debris into the tributaries of the Sacramento, San Joaquin and Feather rivers. The committee also amended Sec. 2, which makes it a penalty to wash debris into the rivers or deposit it in such place from which it is liable to be carried by floods into the rivers, so as to provide that no mining but hydraulic mining by water run through a nozzle and under pressure shall be construed to be prohibited. These amendments were made through Senator Jones, who is a member of the committee. Senator Stanford and Mr. McKenny had a conference in regard to these amendments, and Senator Stanford will move the restoration of the provision for bringing suits by the Secretary of War.

VISALIA was successfully illuminated by electric light for the first time on the 5th. The plant cost \$10,000 and is owned by two of the citizens. The system is the Western Electric, and this is its first introduction in California.

THE Carbon Hill coal mines at Tacoma, W. T., shipped 25,700 tons of coal during June—the largest shipments made since the opening of the works.

in the tanks inside the mills, and is caught in large reservoirs outside. The slimes, never having been worked, are richer than the sands, but the assay values of each class vary considerably among themselves.

After repeated tests of refining machines, including a year's trial at Dayton, the Bonanza firm adopted the process and built a refinery at the Omega mill, near Virginia City, where was treated all the base bullion forwarded by the mills owned by the Pacific Mill Co. The financial results obtained were beyond their most sanguine expectations. We give herewith an engraving of this refinery, showing the general arrangement adopted. Other mills on the Comstock have since made use of the process, which has been described in detail before the American Institute of Mining Engineers by A. D. Hodges, Jr. We shall in next week's PRESS commence a series of articles descriptive of the processes referred to of refining coppery bullion.

ORO PLATA.—The Mohave Co. Miner, (A. T.) says: Charley Maxson has sold out his lease on the Oro Plata mine to good advantage, and with the money he made while working the mine, he has cleaned up a nice little stake.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

## The Pine Creek Mines, Oregon.

EDITORS PRESS:—In reading your journal I have seen nothing for some time with regard to this very promising and growing camp. The two towns, Allantown and Cornucopia, are rapidly merging into one, as they are but one-half mile apart, and already the short space between is lined with cabins. There has been a steady influx of fortune-seekers the past month and our population now is about 1000, with numerous stores, etc., and three butcher shops. Provisions are very cheap, viz.: flour, \$1.25 to \$1.75 a sack; eggs, 20 cents a dozen; bacon, 10 cents per pound, etc. The region being so elevated (4700 to 9000 feet) the snow is slow in departing, and consequently little has yet been done in the mines, almost all of which are several thousand feet above the town. The Whitman, the only mine that has been worked all winter, is showing up handsomely. At the 200-foot level an ore chute has been struck assaying away up in the thousands. Work has been resumed on the Silver Bell, and a pan of the quartz brought to town Monday contained at least \$100 in gold. It is very rich in tellurides. The O. R. N. shipped some ore yesterday. The Dominican, or as generally called the Jack in the Hole, a ledge in close proximity to town, is being prospected by a new tunnel, 40 feet of which is now completed. The owners of the Norway ledge, a very strong vein some three miles distant, have about completed their adit. The "Contact," or as it is generally called, the "big silver mine," being some distance (four miles) from camp and very high up, has not been worked yet this spring, but it is pronounced by experts to be without doubt a true fissure vein, and as far as developed assays up in the hundreds in silver. It is a five-foot ledge lying at the contact of granite and slate, with well-defined walls and gangue of talc and porphyry. It has been developed under the management of the well-known California and Nevada expert, Mr. Robert Kelly, to a depth of 150 feet, and a drift has been run 50 feet on the vein. The assays run from \$50 up to \$700 per ton, and the quartz is enough to make the eyes of a mining man glisten. Messrs. Breck & Co. are putting in a reduction plant on a small scale and are about ready for business. Their works (the Pine Creek Metallurgical Works) include a reverberatory furnace, two-stamp mill and chlorination and leaching apparatus with a capacity of six tons per day. The power is furnished by a 14-foot overshot wheel. Everything is arranged very conveniently and everything is heated by a steam boiler. Their vats for lixiviation are six in number and were mostly built by Messrs. Jewell & Co., of your city, and are first-class in every particular. They have power and mill room for 10 stamps, and undoubtedly will soon put them in. Another year will see "Pine Creek" a booming camp well on its way to a Butte city. More anon.

Yours truly, J. A. STACKLOW.  
Allantown, Union Co., Oregon.

## Siphon Action of Discharge Pipes.

EDITORS PRESS:—In your issue of June 5th there is a description of a draining pump made by the San Francisco Tool Co. and some statements respecting such pumps which many of your readers will construe as coming from myself, because of my connection with that company.

This I wish to correct and to add that I am wholly opposed to siphon action in the discharge pipes of any pump unless unavoidable, as it may have been in the case alluded to.

The statement respecting the arrangement of pumping on this method in Europe "to the exclusion of other methods formerly applied" will be news to those who erect such machinery. The idea is as old as iron pipes, and the practice has fallen into "desuetude" from the face of experience. No cases being given, I am at a loss to know where the plan has been revived.

The agitation of water in passing through a pump of any kind releases air which lodges in the discharge pipes, and unless continually drawn off by some negative pressure, equal to the difference in the water levels, the siphon action soon ceases.

The employment of a condenser or steam ejector to remove this air takes draining apparatus from the field of simple mechanism so desirable in such cases, and offsets the counter-acting advantages.

Instead of such a method coming into use in the Old World, I think no maker of such machinery will, when avoidable, raise water above a discharge level. As before said, I am not aware of the authority on which the statement is made, but must recommend it be taken *cum grano salis*, at least I want no part in its paternity.

J. RICHARDS.  
Pittsburg, Pa., June 25, 1886.

THE South Pacific Coast Railroad Company has received six new passenger coaches from Wilmington, Delaware, two locomotives from the Baldwin Locomotive Works, and six street cars from Newark, Alameda county, for use upon the Telegraph avenue street-car route.

## Park City Mines, Utah.

Mining operations in the hills around the Park, says the *Miner*, may now be said to be renewed for the season in full blast. The snow has almost entirely disappeared from the high hills, and the usual spring drawbacks, occasioned by surface water, are well-nigh over with. The roads were never better than they are now, and no difficulty is experienced in getting fuel and supplies to the mines and hauling ore down to the mills and railroad. Prospectors are jubilant at the indications, and ere long many of them will be working their claims with their hard-earned cash of the winter. Altogether, the prospects of the season's work in the Park are very flattering. Every indication points to a lively boom for Snake Creek district this summer. There are numerous valuable prospects in the above-named mineral section that will come to the front just as sure as fate. The persistent claim-owners and prospectors of

## Snake Creek District

Have stuck by their convictions as regarded the ultimate proof of its richness, and now they are prepared to offer good inducements to investors. Aside from its immense area of mineral ground, it is also known to contain inexhaustible beds of white, black and colored marble. If capital from anywhere is looking for opportunities, we would recommend an inspection of this district, as it is bound to show up astonishingly in the near future. All Snake Creek needs is capital, and capital it is bound to get. We shall review this district in detail in a week or two.

## At the Ontario Mine

Everything is going along with its usual clock-work precision. The broken rod of the Cornish pump has been repaired and the iron column will reach here from San Francisco in a few days. The great pump will be working again very soon. Meanwhile the steam pumps on the three lower levels keep the water down without trouble. The Ontario mill, after having been closed down since the 1st inst., to make the needed repairs and overhauling, will start up about the middle of next week for another year's successful run.

## The Daly Mine

Is now employing about 110 men, and the working of every drift and stope in the mine reveals more and more rich mineral. An average of nearly 20 tons of high-grade ore is shipped to the sampler, and from 50 to 60 tons of ore is hauled to the mill each day. The output of this mine per day approaches 75 or 80 tons. Every move made at the Daly seems to be productive of flattering success.

## The Morgan Group

Is still "tied up" and little or nothing is being done. The company represented by George A. Meears holds possession, and as soon as the pending litigation has been sufficiently cleared up large hoisting works will immediately be erected and developments vigorously pushed.

## At the Anchor.

The present working force numbers about a dozen men, but this number will be increased to 20 or 30 in a few days. No trouble from surface water is now encountered, and the indications may be said to be good. The shaft is down past the 500 level, and more depth is to be attained in hopes of striking the main ore body before very long.

## Work at the Sampson.

The surface water which handicapped work here a few weeks ago is now a thing of the past. In the old workings considerable retimbering is being done, and the prospects are good for a fine showing of this year's work. Giles & Co., who worked the 200 level on a lease, have returned on a recent shipment that show 118-ounce ore. In the tunnel where the main ledge was cut a few weeks ago work is being pushed on the east and west drifts along the foot wall. The ledge has not been cut through yet, but it will average 20 feet in width. A fine body of ore is exposed and it can be advantageously worked when some connections are made and good ventilation secured. Thirty men are employed at the Sampson, but the force will soon be increased and ore shipments resumed.

## The Crescent's Operations.

Work on the Crescent Company's property is being prosecuted with vigor, and the good showing still continues. The Rebellion tunnel is in the hill a distance of about 800 feet and the Etna is in about 900 feet. A large portion of the force is kept at making raises to the surface, and when this work is completed the mine can be better worked than ever. At present 30 men are employed in the mine and 13 are required to load the ore in the cars. An average of 50 cars, or 175 tons of ore, is sent down to the concentrator daily. The total force of the Crescent, excepting the 15 or 20 at the concentrator, numbers over 50 men, and the force is soon to be largely increased. Several claims in the near vicinity are being developed by the Crescent Company also. Crescent stock is now quoted at \$1, with an upward tendency. The outlook for the season's work of the Crescent is very encouraging.

WILL BE FINISHED.—The Cape Cod ship canal, it is again stated, will be pushed through to completion, Fred A. Lockwood, the contractor, having obtained the necessary funds in New York.

## Expositions and Mines.

The Denver *Tribune-Republican* says: In May next, less than one year from this date, a World's Exposition will be held at London, in which the mineral productions and manufactures of every nation are expected to be represented. The United States has accepted an invitation to be represented, and President Cleveland will, from the executive office in the White House, open the Exposition. He will touch a little knob on a machine of American invention, which will set in motion the machinery at the Exposition, over 3000 miles distant.

Eastern manufacturers will embrace the opportunity to show their products, and will be largely represented. Mexico and some of the mining Territories in the United States will make a display of their mineral productions. So far nothing has been done to cause Colorado to be represented. Can the State afford to go unrepresented? It is true that Colorado has had a surfeit of expositions, but the fact is not generally known that a large part of the advancement that the State has made is due to those expositions. The vast canals of the San Luis valley, the Grand, Uncompahgre and, to some extent, the Platte valley, are due to the capital attracted to Colorado by the first exposition at Denver. Over a million dollars is positively known to have been invested in Colorado mines and more in their development, which was attracted here by that exposition. Some of the finest improvements in Denver have been made by men who were first attracted to Denver by that exposition. It is difficult to measure the good it did for Colorado; it is only known that it did much, and no one man knows all the good it did.

It was a grand advertisement, and in this modern age advertising is indispensable to success. The merchant who has goods to sell, the miner who has mines to dispose of, the town, city or State which wishes to attract capital and population, must advertise. Colorado wishes capital and population. It can get both when its natural resources are known. The prospectors and miners want aid in developing their properties; they can get it when capital is brought to the State. Farmers want a home demand for their products, and merchants want to sell more goods. Both can be satisfied with an increase of population. Will any effort be made to attract the capital and population?

No class of people is so much interested in having the State represented as miners, because no class is so much dependent on the investment of capital to make their business as prosperous as it can be. Will they move in the matter? If a fair representation of ores of gold, silver, lead and iron, of clays, of coal and coke, of feldspar, soda and quartz are made in London, it will be an advertisement which would certainly be worth more than its cost.

## Money Wasted in Mines.

The writer had charge of the investigations as to mineral resources of New England which were made during the tenth census of the United States. His inquiries showed that during the last 20 years more than \$4,000,000 had been wasted in utterly hopeless mining schemes within this district, yet this region does not begin to compare in its blunders with many other parts of the United States. The waste of money in mining schemes in various parts of this country which would have been condemned by the advice of such a survey has probably amounted, during the last 30 years, to about \$200,000,000, or many times the cost of a complete national survey. Already we have sufficient evidences that the information given by the survey can effectively prevent wild mining schemes. When the mines of Leadville were discovered, the conditions in which the ore occurred were new to the miners and the blunders great. Immediately on the establishment of the national survey, a competent geologist was detailed to study the district. His reports have formed the basis of exploration and have served to bring the mining of that region from the original speculative state to that of a legitimate industry.

Thus, not only as a means of discovering new resources, but in its work of correlating and controlling the earth industries of the country, the national survey has a field of very wide usefulness before it. Knowledge, such as it can obtain, is beyond the power of individual enterprise to acquire; it ranks in value with the resources of natural defense against foreign enemies; it is, in fact, a means of protection against ignorance, the common enemy of modern progress.

The limits of this article make it impossible to consider the claims of the other scientific departments of the Government upon the support of the public. They all have the same sound basis in that they are doing work which is beyond the power of the citizens or any association of citizens to do, and they are of great value to our modern economic life. This life depends upon an extended and ever extended knowledge of the earth. The best service a government can do for its people is to increase and diffuse this knowledge on which their success inevitably depends.—Prof. N. S. Shaler.

## The St. Regis Country.

John Miller and Jesse Pryer, says the *Cœur d'Alene Record*, walked from their mines in Deer creek, a tributary of the St. Regis, a distance of 41 miles over two mountain ranges, last Monday, and Johnnie's friends had to "head him off" to prevent him from walking on to Thompson Falls for supper. Mike Rochford, Billy Leonard and eight more of their partners are running a cut to their placer diggings on Deer creek and also prospecting for quartz. Mr. Miller favored the *Record* with a short visit and gave us a good many interesting facts about Deer creek and that part of the St. Regis country which he has seen. The valley, or more properly Deer creek gulch, is about 32 rods wide, covered with a vigorous growth of grass, underbrush and strong willows, but few trees. The creek has a fall of about eight inches to the rod. The first discovery of gold was made last fall, and the ground for a distance of 12 miles is staked in 20-acre claims. Not a single pan has been prospected that did not show gold and in about the same quantity, seldom falling below 10 cents and averaging 16 cents of fine round smooth gold to the yard all through from rim to rim on the bars as well as in the bottom. Coming down to the St. Regis river we find a valley somewhat broader than that of the south fork of the *Cœur d'Alene*, say about three-quarters of a mile wide. Unlike very much of the south fork country where the freshness of nature is blackened by burned and fallen timber, the St. Regis retains its primeval forest of bull pine and red fir, standing aloof from each other in their grandeur, admitting the sunshine and the shower and majestically guarding the luxuriant grass and verdure beneath them. The river is somewhat swifter than the south fork and at the present time is swollen beyond its banks and raging more furiously than ever in the last eight years at least. The flood has carried down all the foot logs and bridges for 22 miles, as these gentlemen can testify, and probably the same is true of its entire length. And still, after all the extreme warm weather of the last few days the snow is several feet deep for a distance of a mile and a half over the lowest pass out of the valley, while below the climate is as fine as one could wish. Deer and chickens are plenty, and provisions and supplies are laid down from Horse Plains at about Murray prices. At present the only dealer in goods is a trapper who has lived there eight years and frequently goes out with furs and brings back such supplies as the few miners order. A party of emigrants from Kansas, en route for Oregon over the Mullen road, are camping there for a few days. Quartz prospectors are scattered over the mountains and more will be there when the snow is gone. Some discoveries have been made, but no development beyond that. The rock formation is gray porphyry with an occasional dike of granite and quartzite. Considerable quantities of float quartz is in sight, and since the field to the south of us has been so encouraging to prospectors it is to be presumed that the St. Regis country will be pretty thoroughly gone over.

THE NIGGER PRAIRIE REGION.—John Gurley, who left Murray about the middle of last July on a prospecting trip on the South Fork, called on the *Record* to-day, and in a general way gave us a very candid and highly-encouraging report of the mines near Nigger Prairie. He says that no very great amount of work has been done on any of them except the Hunter, but that a little has been done on a good many, and that in every instance they show highly-encouraging results, and that capitalists are gradually taking hold and that a good deal of development will surely be done this season. He sums up the work on the Hunter as follows: First, a tunnel 150 feet, then a crosscut through the vein to the walls 50 feet, then a continuation of the tunnel 150 feet, then another crosscut which is now 30 feet through a body of good concentrating ore with strata of galena and gray copper, some of which he has been assured and believes assays as high as 3700 ounces. While these facts no longer excite our readers and we do not publish them as late news, since we hear substantially the same reports every day, nevertheless we enjoy having good reports confirmed by this reliable gentleman and to know that his own efforts are likely to find a good reward.—*Cœur d'Alene Record*.

CONSOLIDATED CALIFORNIA AND VIRGINIA.—The official statement of the bullion yield and expenses of the Consolidated California and Virginia mine for May has been received and filed at the office of the company in San Francisco. The number of tons of ore worked at the mills was 12,040, yielding bullion of the assay value of \$147,161.63, which, deducting the discount on silver—\$19,131.01—would leave a net yield of \$128,030.62. The expenses of the mine and mills alone in May aggregated \$137,482.90, or over \$9000 more than the net yield of the mine. The ore worked in June is of much lower grade than that in May, the average value of the battery samples at the Eureka mill last week being \$8.83 per ton. It cost fully \$11.50 per ton in May to produce bullion, the silver portion of which was subject to a discount of at least 25 per cent. Should the grade of ore continue thus low, assessments are not very far off.

## The Butte Copper Mines.

In the Boston *Commercial Bulletin* I read that the Calumet & Hecla can make a handsome profit by selling its copper at 10 cents, while producing it at a cost of seven, and also that Arizona and Montana producers will be compelled to close if 10 cents remains the price, and the market be left to the Calumet & Hecla and those Lake companies that can stand this price.

I am not in a position to speak for the Arizona producers, but as far as Montana—that is, Butte—is concerned, being conversant with the capacity of Montana producers since the first copper was shipped from here, and having been since then a close observer, I might perhaps be able to destroy this comfortable, though false, impression held apparently by the managers of the Lake concerns and by other parties interested in the copper trade.

The Calumet & Hecla may perhaps compel the Parrot Company, with its small ore reserves, and but one mine 800 feet long by 150 feet wide, to close down by reducing the price of copper to nine, or even eight cents, if the shareholders will allow it. But such concerns as the Anaconda or Montana Copper Company could not be compelled to close, even by reducing the price to less than eight cents.

The Anaconda will soon be in a position, by strict economy and after completion of its new concentrating mill—which in itself is a wonder of the age, the largest in the world, and provided with the latest automatic appliances—to reduce the labor charges, and to compete in the cost of producing copper with any concern in the world. At the same time, the Anaconda will be able to double its production, if forced to do so by the further reductions of the price of copper.

It is almost a certainty that the ore bodies in sight at the Anaconda & St. Lawrence mine warrant the same production for five, or perhaps—if the 1000-foot level continues to show as large an ore body as at present—for ten years to come. Besides, this concern could fall back on the other copper mines, indirectly controlled by it, such as Modoc, Mat, Adelaide, Wake-up-Jim, Green Mountain and many others. Most of them carry silver, and it is only a question of time when they will be prepared to desilverize on a large scale in this country, instead of allowing the English smelters to get the profits on the work.

In my last letter I wrote that the Anaconda plant would be enlarged by a 40-stamp mill, to work the silver ores of the surrounding silver mines, thus reducing general expenses. There is a large field left for such operations, and I believe that this is a move in the right direction, and very creditable to Manager Daly.

You may rely on it that the Anaconda cannot be frozen out by the Lake companies whatever moves they may make, or however they may surprise and demoralize the copper markets.

Neither can they do it with the Montana Copper Company, should that company decide to run. The greater part of its mine has hardly been opened and worked. For instance, in its West Colusa and Liquidator mine the rich surface ores between the 400-foot level and the surface are almost intact, and are estimated at 500,000 tons in sight, averaging from 15 to 17 per cent of copper and carrying some silver. Should the directors follow the advice of their Butte manager, they could produce copper cheaper than any other Butte concern. For some reasons, however, due probably to the circumstance that the controlling interest is in the hands of copper dealers who have also other interests, only a little development work is done at the Colusa mine, and most of the furnaces are lying idle. Four furnaces work some copper matte high grade in silver, to clean up silver custom ores on hand at the plant. Altogether about 200 tons of such matte will be made, and then these furnaces will be closed also.

In fine, I repeat that there can be no freezing out of these two companies and of some other smaller concerns here. Besides, in a year or two fuel will cost only one-half its present price. The Northern Pacific Railroad will have direct communication with Butte by the 1st of August, and be a strong competitor of the Union Pacific Railroad; also, a third railroad is surveyed to Butte and will no doubt be completed before the end of 1887. It is proposed to run the railroad north from Helena to Fort Benton, and to connect it with the Canadian Pacific, while it will extend from Helena south directly to Butte, passing the rich silver-galena mines at Boulder and Basin. The projectors of this road are wealthy capitalists.—*Cor. Engineering and Mining Journal.*

**LEACHING ORE.**—The Southern Utah *Times* has the following list of prices given for crude ore by Nesbit, Bailey & Co., delivered at their leaching works:

Oz.	Per ton.	Oz.	Per ton.
10.....	\$1.00	18.....	\$4.50
11.....	1.25	19.....	5.00
12.....	1.50	20.....	5.50
13.....	1.80	21.....	6.10
14.....	2.10	22.....	6.70
15.....	2.45	23.....	7.30
16.....	2.85	24.....	8.00
17.....	3.40	25.....	8.75

The above prices are subject to fluctuations of the market. The price-list for ores of higher grade is not yet complete.

## New Field for Prospectors.

J. F. McLinn and D. D. Zook called on the *Record* yesterday and gave some interesting facts about a portion of country lying between Vermillion and Swamp creek on the Swamp creek side and north of Clark's Fork some 35 to 40 miles northwesterly from Murray. The nearest route to the foot of the mountain which our narrative will be limited to is by the Trout creek trail, a distance of not less than 35 miles across Bald mountain, and in a line due nearly northwest. By the way of Thompson Falls, which at present is the easiest route, the distance is about 60 miles. The mountain rises in abrupt, almost perpendicular, craggy walls or benches, 75 to 100 feet or more in height, with marshy plateaus considerably broken and over-run by slides. These benches rise without marked variation for a distance of 12 miles to the summit, which is about the same height as Bald mountain, say about 6400 feet above the sea. The water, which comes plentifully from springs in the rocks, is soft and warm, and so highly impregnated with mineral that it is slippery, especially near the foot of the mountain, which is extremely difficult of ascent, owing to the almost perpendicular places. The marshy flats extend to the very top, where there is a big swamp. These flats are covered with grass and several bushes resembling chaparral, and are infested with black gnats and mosquitoes, which keep up a constant torture. Large trees standing well apart are distributed all over. The object of Messrs. McLinn and Zook being to hunt for mineral, they would of course endure almost any hardship to get ahead of less ambitious adventurers. But to their astonishment they found not only mineral in the rocks but pieces of pure metal and ruins of a crude smelting arrangement which had produced it. About this place they found remnants of plates, camp kettles, frypans, gold-pans, remnants of several books so completely matted together and decayed that scarcely any idea of their character could be reached, although the title of one could be distinguished as "Pleasant Days." On the top of the mountain a shaft had been sunk 30 feet. From the rottenness of stumps and general condition of what they saw, this camp must have been abandoned 25 years ago, and could not have been kept up many days. It probably dates about 1862, when the Government trail to the Kootenai mines was built, as previous to that time the Indians had possession of the country. There are very few prospectors and hunters trying their luck in this new field. No trouble in finding plenty of game. Deer are plenty, and to show that bear are not scarce they report that two men recently killed eight in a single day. The country rock is gray and black granite and porphyry. The leads are from one and a half to eight feet wide and carry gold, silver, copper and lead, the gold apparently increasing with the height of the hill and being also more prominent on the eastern slope. One place shows iron croppings 40 feet wide. The course of the veins is southeast and northwest. They brought in a box of fine-looking specimens of ore and also lead from the old smelter. Assays have been made, but the locators choose to withhold results. Other parties have gone from Murray, and we expect to hear more from these prospects.—*Cœur d'Alene Record.*

**THE SILVER DOLLAR.**—Of all the silly things thrust in our faces from day to day, the slush about the silver dollar being only worth 80 cents beats all. Will the fools never learn anything? The paper in a greenback dollar is not worth 80 cents, is it? Why not make this fact a pretext for retiring them all? True enough, the Shylock crew hate the greenback and want to destroy the last one, but who ever heard of any one arguing that because the paper upon which they are printed was not worth a dollar, therefore destroy them? That is "too thin." Everybody could see through that. And yet the argument against the silver dollar is exactly the same. Will the people never learn that money is one thing and the material used in making it another? The Shylock crew know this. We can't give them credit for being such fools as not to know it. But it is their aim and business to keep the masses in ignorance of the true nature of money. As Judge Tiffany says: "Truly speaking, there is no such thing as a gold dollar, a silver dollar, or a paper dollar."—*Elk Mt. Pilot.*

**THE NEW RAILROAD SHOPS.**—The new building is fast assuming gigantic proportions, says the *San Bernardino Index*. The framework for the second story will be in place to-day. The brickwork for the foundation of the kitchen and pantries is completed. The main passenger depot will be 40 by 138 feet, two stories in height, with a brick extension, 36 by 36 feet, all fronting on Third street, opposite the present temporary depot. The first story will be 16 feet in height, the second 14 feet. Covered porticos, 12 feet wide, of a new and elegant design, will extend the whole length of the main building on the south side on the first and second story. In the main building (ground floor) will be located the passengers' waiting-room, ticket and other offices, baggage-room, dining-room, etc., and the brick building adjoining will be devoted to the kitchen, bakery, also bed-room, etc., for use of employees of the dining-room. The second story of the main building will be occupied by the division head-

quarters and offices of the company. The total height of the building will be 40 feet; the material wood and brick. The freight depot will be situated 350 feet west of the passenger depot and division headquarters. Its dimensions will be 179 by 40 feet, exclusive of platforms. A large icehouse and a brick building for laundry and closets, 23x30, will be built between the two depots. The roundhouse will be 330 feet in diameter, with 24 stalls. There will be a car shed 40 by 300 feet; also a coal-bin 1050 feet long, of sufficient capacity to accommodate a whole cargo. The machine shops will be 100 by 150 feet; car shops same size; large transfer table; blacksmith shop 80 by 100 feet; boiler shop 50 by 80 feet; foundry 50 by 100 feet; pattern shop 50 by 50 feet; storehouse 40 by 80 feet, a three-story brick. There will also be built offices for the master mechanic and other officers in charge of the division shops.

## The Mother Ledge.

The gold deposits of the San Gabriel canyon have long been known. In 1857 a rush of miners took place there, and for seven years upward of 700 men kept themselves hard at work. They labored under great difficulties. The scarcity of water compelled them to pack pay-dirt on their backs for miles to the shallow stream of water. Still they labored, and upward of \$2,000,000 in dust was taken out. A mining excitement in Arizona, in 1864, caused a general stampede to that section, and since then but little work has been done there. The question has been asked many times, "Where does the placer gold come from?" Every miner says, "from the mother ledge," and many a miner has looked for the mother ledge of the San Gabriel canyon. It was way up somewhere around the slopes of Old Baldy.

The "mother ledges" are curious formations. The one at Cœur d'Alene was discovered, and proved to be very rich. It was about 300 feet long, and stuck right out of the side of the mountain. The corrosion of the elements for ages had worn off its face, and cloudbursts and floods had carried the pieces of float down the canyons till its wealth was scattered along for miles.

The writer has seen similar indications of a mother ledge in the famous Horseshoe Bend in the Quijotoa mountains. As early as 1774 Padre Lopez worked these mines. The placer dirt was washed at the water tanks, while the silver ore was shipped to Muleje, Lower California, for reduction. Somewhere up in the Horseshoe Bend is the "mother ledge" from which this placer gold has come, and some lucky prospector will find it.

Two prospectors of Los Angeles, Peter Walters and John Peterson, left to-day, determined to find the mother ledge of the San Gabriel canyon if it is possible. They took with them two months' provisions on six burros. They are the gentlemen who discovered the gold mines in the Cargo Muchacho mountains, west of Yuma, two years ago, and sold them for a handsome cash price. Mr. Peterson met with an accident last summer by which he lost his left eye, but his right eye is as good as ever, and knows gold rock whenever it is in sight. They will explore the Sierra Madre range clear over to the Mojave desert.—*Los Angeles Express.*

**A MYSTERIOUS MINERAL.**—It will be remembered that some weeks ago the *Inter-Mountain* published a short article concerning a strange mineral found in the Bell mine, near Sheridan. Max Meyers writes us that since that time the mineral has been examined by Prof. Baird, of the Smithsonian Institute, who says that it is the somewhat rare species tetradymite, the telluride of bismuth, containing from 35 to 50 per cent tellurium, the remainder being bismuth and occasionally a small amount of sulphur of itself. The professor also states that the samples sent him are similar to the tetradymite found in the Highland district of Montana at the Uncle Sam lode. Samples to the extent of 75 or 100 pounds will be sent to the institute during the summer, as developments may justify, to further determine the presence of any other tellurides. He says it may be possible that some of the very rich tellurides, such as occurred in Colorado, may be discovered. In assaying this tellurium to ascertain the amount of gold it contained, he says an enormous excess of lead is required in order to get accurate results. As before stated, the mine producing this ore is the Bell mine, and is located on the range of mountains between the north fork of Mill creek and Willow creek, and is owned and worked by Bush & Meyers. Late developments are very encouraging. All practical miners and mining men are admitted to all parts of the works; all others are excluded.—*Butte Inter-Mountain.*

**SAN DIEGO GOLD.**—The *San Diego Sun* says: "Milton Santee's discovery of rich quartz near Julian, and recent strikes at Jacumba and in the vicinity of Jamul, have created quite an excitement in mining circles. Signor & McNamara report that at Jamul, the Indian squaws are taking out from \$2 to \$3 per day by simply washing the soil in prospecting pans. A party from this city went out to Jamul yesterday, and will endeavor to locate the ledge from which the gold deposits come."

## Ketchum's Smelter.

The Philadelphia Mining and Smelting Company, in the Wood river region, Idaho, has started up its smelter. The *Wood River Times* says:

The works are situate on Warm Springs creek, near its confluence with Wood river and close to the depot, from which a side track runs to rooms where ore and supplies are deposited. The works were begun in 1881, from which time to this hour every improvement known to the scientific world has been added, and will be added whenever occasion offers.

The ample grounds upon which the "smelter" is located belong to the company. The buildings and improvements, in brief, consist of five roasting furnaces, with a capacity of 40 tons per day of working hours; four smelting furnaces with a capacity of some 60 tons each per day; 20 charcoal kilns with a capacity of 40,000 bushels at one charge; scales commensurate in capacity with the needs of such an establishment; stables, out-buildings, lodging-houses for 80 men employed about the works and suitable, well-arranged offices for the several officers of the company.

In the yards are great quantities of flux and charcoal; the latter easily burned from timber, floated upon Wood river from any distance and from its tributary stream—Warm Springs creek—a distance of 14 miles. There is not and never can be a lack in the fuel department.

June 16th the "roaster" was fired up. The company own numerous mines upon which they employed last year 200 and odd men. These mines, with an equal force, they will work from this day on. The Silver Star, owned by Messrs. Rhodes and Borie, of Philadelphia, is probably the most promising property of all those owned by these gentlemen, separate and apart from the company's properties. Its ore, with those of numerous other mines belonging directly to the company, or to gentlemen, part owners of company stock, as well as outside ores, will be operated at the smelting works.

"We are here to stay, sir; we mean business. We will duplicate any price for any class of ore that the country produces. We pay cash, and propose not only to keep these works busy all the time, but to increase their capacity whenever the ore production of the mines warrant it." This is the language of the officers present when the *Times* man visited them yesterday. They proved that they meant what they said.

The ore from the Silver Star has been contracted for at \$10 per ton, freight, delivered at the works. The road to that mine and its surroundings is not yet completed, but will be soon. The road to Germania Basin is practically open. Smoky District ores are pouring into the rooms of the Philadelphia Company. Those from the Sawtooth and surrounding districts will, if the owners see fit to sell, find a market there. The company propose to buy ore as long as they see 100 cents for \$1 expended. Their furnace starts next Monday. There are 500 tons of ore now in the plant, and great quantities on the dumps of the company's mines.

**SWAGGER MINING DISTRICT.**—A meeting of miners and mine-owners has been held at Hutton's Station, says the *Bodie Miner*, for the purpose of reorganizing the Swagger mining district. Norman Hutton was elected chairman, James Andrews secretary. On motion, it was ordered that the Swagger mining district be reorganized with the following boundaries: Commencing at the mouth of Murphey creek, at the crossing of the East Walker river toll road, and following said road south to Main street, in the town of Bridgeport; thence westerly in an air line to the mouth of the Buckeye creek canyon; thence up Buckeye creek to a point south of the headwaters of the Middle Walker river; thence north to said river, and down said stream to the point of intersection with the West Walker river; thence down the West Walker river to a point where the east and west line of Townships 6 and 7, north, crosses said river; thence following said line east to the summit of the mountains between the Walker rivers; thence south along said summit to the headwaters of Murphey creek; thence down Murphey creek to the place of beginning.

**SCULPTURE IN CALIFORNIA MARBLE.**—Morton Edwards, the sculptor, has cut a bust of Alex. D. Sharon from Inyo county marble, which is the first attempt ever made to use California marble in sculpture. In the case of Mr. Sharon's bust the trial has proved the excellence of the material for the purpose, and it is quite probable that in future considerable quantities of California marble will be utilized for artistic uses. Mr. Edwards has been awarded the contract for a large statue of the Savior on the Cross, seven feet six inches in height, for the new cathedral on Van Ness avenue.

**THE Genesee river** is surprising manufacturers along its banks, by its increasing volume of water from year to year. Some years ago, in common with other streams of the State, the water diminished, and the mills and factories that had depended on it for power were obliged to use steam. The *Rochester Democrat* says that millers who have not used their wheels for years are getting back to them, much to their financial advantage. No explanation is given for the condition of the river.

## Passing Events.

Silver has gone down lower than ever, as our market reports show. But wheat has gone up in England, and transactions in the Indian markets are likely to raise the price of silver again before long.

The gradual adoption of the system of drift mining in the auriferous gravel fields of California is in a measure solving the much-vexing debris question. We present in another column some figures showing the cost of work by this system, which will interest owners of claims worked in this manner.

Private letters to a party in Candelaria from Aurora state that the English company which lately took hold of the mines in the latter camp are somewhat discouraged at the outlook, alleging there is nothing in the mines. This, if true, will be a great disappointment to the owners of other mines in that region.

The strike among the iron-workers in this city still continues, with no new features to report. No compromise or arbitration has taken place, and at present both sides seem determined to win.

There is little to report of the general mining situation outside of what we give in our usual mining summary. The news from the Comstock is rather encouraging, however, good ore having been found at the great depth of 320 feet.

## Mining Engineers.

A good deal of unfair criticism is indulged in against the profession of mining engineering because of blunders and mistakes made by men who are supposed to belong to it. But it should be remembered that not all who call themselves mining engineers have a right to the title; and before the profession is misjudged the standing of the individual should be investigated. We have in mind numbers of cases where the title has been appropriated by men without the slightest technical knowledge, or any practical training, but whose "cheek" has carried them through with doubtful enterprises. Men who have held bonds on mines and wanted to sell them have written reports to which they have signed their names, with the added initials of M. E. Others have bloomed out as full-fledged mining engineers on the flimsy basis of having compiled statistics concerning mining products; people who are simply assayers have, after examining a vein or two, taken the title as their own; and hundreds have traded on the gullibility of human nature by the magic words of "mining engineer" added to their names.

None can deplore this state of affairs more than the bona fide mining engineer. He sees an honorable profession scandalized; he sees the title used to promote schemes that no decent man would countenance; he knows his profession is injured, and its good name dragged in the dirt. But there is no remedy at hand in this case. In the medical profession if people assume a title wrongfully, the law steps in and stops it. But there is nothing to prevent any man calling himself a mining engineer who sees fit to do so. Mine superintendents, foremen, assayers, amalgamators, clerks, middle-men and others assume the title, and use it for their own advantage without the slightest right. We have seen reports made and signed by men as mining engineers who had no knowledge of mining whatever outside of that gained in promoting the sale of properties. And not once, but often. As a consequence, buyers who rely on reports from such people are apt to have their confidence abused.

There are, of course, in the ranks of this, as in other professions, men who do not deserve to belong to it; who will use their opportunities to "put money in their purse," irrespective of who is injured by it; men who will call themselves "experts," without expert knowledge. But these are the exceptions. The profession is an honorable one, and those belonging to it are mainly men of education, integrity and position. People who are buying mines can readily find mining engineers who will faithfully and correctly perform the duties assigned them, and in whose judgment they can confide. Some are specialists in the different branches of the profession, having made one department a study, and those who have gained reputation for these things are not apt, for temporary gain, to report outside the facts. But because a few renegades in the profession and a lot of others who do not properly belong to it have made mistakes or done dishonest acts, all the mining engineers of the country should not be condemned wholesale.

## Mining Accidents.

Peter Nichols last week received painful injuries while mining in East Calico, San Bernardino county. A portion of an embankment fell upon him, inflicting a number of cuts on the head and various parts of the body. He will probably be laid up for several weeks.

John Wright, a stockholder in Gover Mining Company, Amador county, met with a sad accident on Friday of last week. He came up from the city on a visit to the mine, and went down the shaft to inspect the underground works. On ascending the shaft in the skip, he threw his head up in some way that he received a blow which knocked him into the skip. In falling, he threw his right leg out, which was caught in the shaft timbers and fractured in two places—at the ankle and just below the knee. He also sustained internal injuries, though it is believed not of a serious nature.

David Bohm, a miner working in the Jefferson Consolidated mine, about three or four miles north of Six-mile canyon, in Flowery district, was found dead Sunday morning in the mine, evidently from an overpowering inhalation of powder smoke used in blasting.

## Drift Mining.

The importance of drift mining is largely increasing in this State, owing to the much vexed debris question, and the necessity of many hydraulic mining claims, resorting to the system to avoid injunction. It takes the place of hydraulic mining in places also where water is scarce or there is no dump room, and where the deposits are low, and it would be impracticable to move the whole by piping. The system is carried on more like vein mining than hydraulicking, although it is only used in gravel. The deposit is opened by tunnel, shaft or incline, developed by crosscutting, and the pay streak taken out. The pay streak generally consists of about three feet of gravel lying immediately on the bedrock, with the upper portion of the bedrock itself to a depth of from a few inches to sometimes three feet. The gravel is shoveled into hand-cars and wheeled to the mouth of the tunnel, or loaded in buckets or "buggies" and carried to the bottom of the shaft and hoisted out. The gravel is washed in sluices, though sometimes the cement is crushed in stamp mills. In the underground workings careful timbering is required, and in breasting out the gravel, pillars are left protecting the main galleries, or square sets of timbers are introduced, which are filled with waste. In most places blasting is practiced, but in many mines the gravel is soft-picking ground, and pumping is often required.

Some of the California mines have yielded largely, though it is difficult to get accurate results. Some returns, however, have been collected by the census officials, as may be seen from the following specimen cases.

PRODUCT OF SPECIMEN DRIFT MINES.			
Mine.	Locality.....	Length of Claim, Feet.	Yield per Linear Foot.....
Hidden Treasure.....	Placer Co.	10,560	\$294.00
Bad Mountain.....	Sierra Co.	7,500	464.00
Hawkeye.....	"	800	437.50
Eclipse.....	"	1,560	432.05
Monumental.....	"	1,040	312.00
Pittsburg.....	"	860	506.00
Union.....	"	2,400	625.00

The conditions which determine the expense of mining on this plan vary widely. Favorably situated deposits, requiring neither hoisting nor pumping appliances, can be worked at extremely low cost; but if the ground is loose, water troublesome, and pay irregularly disposed, the expenses are increased. Thus, while gravel yielding a trifle over \$1 per yard is profitable under certain conditions, in other localities an average of \$3, \$4, \$5 or \$6 per yard will barely cover expenses. At one mine in El Dorado county where the cement is crushed by stamps, gravel yielding \$3 per ton pays; at another, in Placer county, where crushing is also practiced, gravel of the same grade yields a handsome profit above cost of milling and mining. An average of \$2 a ton pays all expenses at another Placer county mine.

An analysis of the cost of mining in a series of mines in McAdams and Indian creek districts, Siskiyou county, compiled from census reports, is appended. These mines are shallow workings, from 28 to 74 feet in depth, the shafts penetrating a light wash and tailings. The "pay" is quite regular, lying in and on the bedrock, and is stoped out on the long-wall system, hoisted to the surface in buckets by horse-whims, and washed in sluices near the shaft mouths.

COST OF DRIFT MINING IN McADAMS AND INDIAN CREEK DISTRICTS, SISKIYOU CO., CAL.

	Cameron Mine	Carroll Mine	Hardy Mine	Lincoln, Hart & Henry and Oak Grove Mines	Williams Mine

STATE MINERALOGIST WM. IRELAN, JR., has been inspecting the gold mines in Tuolumne county. He was thrown from a stage near Sonora and was quite severely injured, so that he has been compelled to return to the city for awhile. As soon as he is fully recovered he will resume his investigation of the gold mines of this State.

## The Comstock.

Although none of the Comstock mines have paid dividends for a long time, work is vigorously prosecuted all along the lode. Last week pretty good ore was found as deep as the 3200-foot level station on Chollar ground, and the miners are hopeful that it will develop into a good rich body. The vein matter is very promising. It is somewhat the fashion in other camps to belittle the Comstock, now that it has stopped paying any big dividends, and its magnificent record seems almost forgotten. At the same time many of the mines are turning out an amount of bullion that in other camps would be considered large. True, in most cases, it does not pay the heavy expenses of deep mining, but in other camps we hear more of the yield than of the cost; while here we are told more of the cost than of the yield. If, however, another bonanza should be struck, the regular "I told you so" would be heard from many quarters. And one more bonanza, at great depths, would bring back confidence in the whole lode. Shares would go up booming, and the value of all the other mines be largely increased.

The men who are managing and working these mines have plenty of pluck and energy, and have the courage to work against difficulties which elsewhere would have resulted in abandonment of the properties entirely. The expenses of mining at great depths are very large and difficulties are encountered which in shallower mines are never met with. Immense sums are paid out for material, hoisting, pumping, supplies, milling, etc., in mines which have not paid expenses for years. It takes a good deal of pluck to work ahead under such circumstances, and a good deal of money, too. The labor bills alone are very large. For instance, the pay-rolls of the Comstock mines for last month foot up as follows:

Con. California and Virginia.....	\$28,573 00
Gould and Curry.....	3,351 00
Hale and Norcross and Savage.....	10,159 00
Mexican.....	829 00
Ophir.....	4,308 00
Sierra Nevada.....	3,639 00
Belcher.....	10,048 00
Chollar and Combination Shaft.....	19,220 00
Crown Point.....	12,816 00
Union Consolidated.....	945 00
Utah and Union shaft.....	290 00
Alta.....	1,500 00
Justice.....	300 00
Kentuck.....	9,000 00
Six-mile Canyon pay-rolls.....	15,000 00
Osbiston shaft.....	8,183 00
Yellow Jacket.....	16,570 00
Carson river mills.....	56,000 00

Total.....\$200,369 00

When such sums as these are monthly paid out for labor alone in one camp, it is evident that the camp is by no means "dead," as it is the fashion to say the Comstock is. The old lode may at any time take up its course of bullion production again and prove for deep mining all that its friends claim.

## Common Sense Geology—No. 1.

[Written for Press by JUSTIN CHENOWETH.]

Prefatory to what I propose offering to the consideration of a reading and thinking public, I will state that 27 years ago I possessed only such knowledge of geology as ordinary general readers usually acquire. About that time an accidental circumstance directed my attention especially to the subject. Since then, with good opportunities for observation, I have devoted myself to the study of the principles pertaining to that pretended science in so far as an active outdoor, breadwinning life would permit. I have long since become fully convinced that the entire system, as now formulated, rests on a fallacious basis. I am aware that by many persons it will be regarded as the height of presumption for an obscure person like myself to controvert the dicta of the scientific world in this matter; but truth, whencesoever its origin, is irresistible, and once uttered will eventually prevail.

The allegation that a certain theory is generally accepted by savants is a very weak argument in support of its truth. Though occasionally disputed, the Ptolemaic system continued to be orthodox in astronomical science during a period of 1600 years. In relation to Galileo's discoveries, in Johnson's Cyclopædia the following passage occurs, viz.: "But the first to excite persecution were the men of science themselves, who were unwilling to be suddenly convicted of ignorance, to confess their mistakes, and to be sent back to school. It was these very men who forced Galileo to fly

from Pisa and seek the protection of Salviati, when he ventured to contradict by experiments made from the top of the Leaning Tower, the theories of Aristotle which declared "that the velocity of the motion of falling bodies is in proportion to their weight." Subsequently finding the savants impervious to argument, he assailed them with ridicule so vigorously that they were fain to shelter behind the power of the Inquisition. The treatment which Galileo received from the rulers of the Romish Church will ever remain a stigma on their character; but the more reprehensible persons are the scientists who instigated the diabolical persecution which he suffered.

Another illustration of the fallacious prejudice of the mass of scientific men, when once settled in a groove, is afforded in the fact that for half a century after Newton had mathematically demonstrated the correctness of his theory of gravitation the mathematicians of England, along with those of the continent, persisted in their efforts to refute it.

The entire system of geology rests on the assumption of a general principle, that all strata of aqueous origin was originally deposited in a horizontal position; that where they now appear in a position different from that it is the result of a disruption of the earth's crust while the main

body was in a molten state. I feel well assured of being able to present at this time facts and arguments tending to disprove the correctness of this assumed principle which geologists can neither gainsay nor refute.

Fig. No. 1 of the accompanying engravings is drawn from a photographic view of one side of a cut for a roadway in the town of Nanaimo, in British Columbia. That portion of the cut where the view was taken is of a stony appearance, but not so hard as to require blasting for

the purpose of removal. Farther down—that is, to the right of the view—the cut was through hard conglomerate in thin layers, inclined at angles between about 30 and 40 degrees. That part of the view marked A shows a distinct line of stratification forming a sharp apex.

FIG. 1.—APEXED LINE OF STRATIFICATION.

FIG. 2.—BENT STRATUM.

It is proper to explain here that the engraver has not very correctly copied the photograph from which Fig. 1 was prepared, in that the stratum, A, is represented as being fractured and disconnected at some points, while in fact

it is continuous and unbroken. On the opposite side of the cut the ground has precisely the same appearance. There is not any break nor the least indication of compression in the crooked strata, both of which would certainly have occurred had it been bent

FIG. 3.—STRATA INCLOSING UNCONFORMABLE STRATUM.

at such sharp angles. It was undoubtedly deposited by the action of water in the shape in which it now appears.

Fig. 2 gives a view of a portion of the wave-worn beach of Nanaimo harbor. A

and C represent strata of conglomerate nearly horizontal in a line with the shore, and parallel with each other inclined slightly toward the water, while B represents an intermediate formation of this material laminated or stratified at considerable inclination. The stratum inclosed between the parallel strata of conglomerate must inevitably have been originally deposited in the inclined position in which it now appears in the figure.

Fig. 3 gives a view of the same beach a short distance from where that of Fig. 2 was taken. It represents a thin stratum of conglomerate nearly horizontal in a line with the shore, slightly inclined toward the water and resting on material somewhat softer and finer grained. At the point B the same stratum turns abruptly down at an angle of about 60°, while another formation precisely similar in aspect to that on the left of B, abuts against the downwardly inclined stratum and continues on to the right, as shown by C. It is necessary to make an explanation of Fig. 2 the same as that given of Fig. 1, with regard to the error of the engraver. The stratum A is represented as being broken and disconnected at the point B, while it is in reality continuous without the slightest indication of fracture at the point where the direction is changed so abruptly. About 200 feet up the

sloping hill, and about 100 feet to the right of the point B, a mining shaft was sunk to a seam of coal. Followed to the left, the seam thinned out, disappearing entirely, rising as it did so, in correspondence with the downward inclined stratum shown on the beach. A tunnel about 20 feet

long cut through solid rock intersected coal to the left of B, on nearly the same level as it was found in the shaft. It will thus be seen that here was a fault unmistakably of deposition instead of disruption, by which latter means geologists aver they are always produced.

It is clear to the observer that the material which formed the seam of coal which was long since mined out, and also that of the rock which inclosed it, was being carried from the southward (which is to the left in the view), the deposition temporarily terminating in a bold talus at the point B, and afterward continued in the same manner and from the same cause which produced the preceding deposit. Illustrations of the subject which I am now presenting may be observed on a larger scale in a rock bluff on the outer side of an island which forms Departure bay near Nanaimo. At one point, where the face is nearly perpendicular, about 100 feet high, composed of hard sandstone without flaw or fracture of any kind visible, the line of stratification at the top is nearly horizontal, while on a clearly defined vertical axis, before reaching the water, it has on one side attained an angle of fully 45°; but on the other retaining nearly the same horizontality as at the surface. I did not procure views there for the reason that they would have to be taken from a boat, and the occasions are rare when the water may be found sufficiently quiet to succeed in that way.

### Assaying with the Horn Spoon. No. 2.

[Written for the PRESS by ELBERT C. VAN BLARCOM.]

The principle involved in this method of assaying, is separation of the component minerals and metals by means of the difference in their specific gravities; hence, it follows that this method of assay is applicable to any ore in which the valuable mineral element is of greater specific gravity than the gangue.

The specific gravity of some of the more prominent gangue rocks is as follows:

Silica.....2.5-2.8  
Lime, carbonates.....2.5-3.1  
Oxide of iron.....3.4-3.95  
Oxide of manganese.....4.08-4.36  
Slate, clay shale, etc. (alumina rocks).....2.5-3

A comparison of the accompanying table will show at a glance the ores to which assaying by the horn spoon is applicable. The mineralogical table has been compiled to show the specific gravity, color, etc., of some of the more important minerals and metals, and will be found valuable for reference. (See preceding column).

Table showing Specific Gravity, Color, etc., of More Important Minerals and Metals.

Metal.	NAME OF MINERAL.	COLOR.	COLOR IN POWDER.	HARDNESS.	SPECIFIC GRAVITY.	PER CT. OF METAL.	REMARKS.
Alumina.	Corundum.....	From blue to black.....	.....	9.	3.9-4.16	53.2	Used for pointing diamond drills.
	Spinel.....	From red to black.....	.....	8.	3.5-4.1	72.	
	Cryolite.....	Snow white.....	.....	2.5	2.95		Iceland spar.
	Alunite.....	White, grayish or reddish.....	.....	4.	2.58-2.75	37.1	Alum stone.
	Turquoise.....	Bluish green.....	.....	6.	2.6	46.9	
	Antimony.....	Tin white.....	.....	3-3.5	6.6-6.75		Native antimony.
	Valentinite.....	Grayish white.....	.....	2.5-3.	5.67	88.56	White antimony.
	Stibnite.....	Lead gray.....	.....	2.	4.5-4.62	71.8	
	Arsenite.....	Tin white.....	.....	3.5	5.65-5.95		Native arsenic.
	Orpiment.....	Bright yellow.....	.....	1.5	3.4	61.	
Bis. Arsen. Anti. muth. to. mony.	Bismuth.....	Bright red.....	.....	1.5	3.35-3.65	70.1	
	Bismuthinite.....	Silver white with tinge of red.....	.....	2.5	9.7-9.8		Native bismuth.
	Tetradymite.....	Lead gray.....	.....	1.5	7.2-7.9	51.9	Sulphide of bismuth.
	Copper.....	Pale steel gray.....	.....	2.5-3.	8.84		Native copper.
	Chalcocite.....	Blackish lead gray.....	.....	2.5-3.	5.5-5.8	79.8	Copper glance.
	Chalcocypite.....	Brass yellow.....	.....	3.5-4.	4.1-4.3	34.6	Fool's gold.
	Bornite.....	Copper red to pinchbeck brown.....	Pale grayish black.....	3.	5.	55.8	Variegated copper pyrites.
	Tetrahedrite.....	Steel gray to iron black.....	.....	3-4.5	4.5-5.12	Variable	Gray copper.
	Atacamite.....	Green to blackish green.....	.....	3-3.5	3.75-3.9	11.25	
	Cuprite.....	Various shades of red.....	.....	3.5-4.	5.85-6.15	88.8	Red oxide of copper.
Copper.	Olivine.....	Olive green.....	.....	3.	4.1-4.4	49.9	Arseniate of copper.
	Malachite.....	Light green.....	.....	3.5-4.	3.7-4.	63.9	Green carbonate of copper.
	Azurite.....	Deep blue.....	.....	3.5-4.5	3.5-3.85	61.5	Blue carbonate of copper.
	Chrysocolla.....	Bright green, bluish green.....	.....	2-4.	2-2.4	40.3	Silicate of copper.
	Asbolite.....	Bluish black to black.....	.....	1.5-2.	2.95	18.9	Earthy cobalt.
	Erythrite.....	Peach red, occasionally greenish.....	Lavender blue (dry).....	.....	.....	29.6	Cobalt bloom—Peach blossom ore.
	Arsenopyrite.....	Sometimes yields from five to six per cent. of cobalt.....	.....	5.5	4.3-4.6		
	Chromite.....	Iron black and brownish black.....	Dark brown.....	.....	.....	.....	
	Chrome Ochre.....	Yellowish green.....	.....	2.5-3.	19-20.		Generally contains about 2% of impurities.
	Gold.....	.....	.....	4.5	7.3-7.8		
Co. min. bath.	Iron.....	Brass yellow.....	Brownish black.....	6-6.5	4.8-5.1	46.7	Iron pyrites.
	Pyrite.....	Bronze yellow.....	Dark grayish black.....	3.5-4.5	4.4-4.65	60.5	Magnetic pyrites.
	Pyrrhotite.....	Silver white.....	Dark grayish black.....	5.5-6.	6.3	34.4	Mispickel—often carries gold.
	Arsenopyrite.....	Dark steel gray to iron black.....	Cherry red or reddish brown.....	4.5-5.3	5.5-6.5	70.	Specular iron ore.
	Hematite.....	Iron black.....	.....	5-6.	4.5-5.	60-70.	Titanic iron ore.
	Monacanthite.....	Iron black.....	.....	5.5-6.5	5-5.1	72.4	Magnetic iron ore.
	Magnetite.....	Iron black.....	.....	5.5-6.5	4.85-5.1	Variable	Generally associated with ores of zinc.
	Franklinite.....	Black to ochre yellow.....	.....	5-5.5	3.6-4.	59.8	Brown hematite.
	Limonite.....	Black to ochre yellow.....	.....	1.5-2.	2.66	31.69	Peacock iron ore.
	Vivianite.....	Deep blue to green.....	.....	3-4.5	3.7-3.9	54.2	Spathic ore—Iron carbonate.
Iron.	Siderite.....	Light gray to brown.....	.....	.....	18.56		Native mercury.
	Mercury.....	.....	.....	.....	.....	64-73.	Contains from 27% to 36% silver.
	Native Amalgam.....	Bright red to brownish red.....	Scarlet red.....	2-2.5	8.5-9.	86.2	
	Cinnabar.....	Light yellowish or grayish.....	.....	1-2.	6.48	84.9	Horn quicksilver.
	Calomel.....	Reddish brown to brownish black.....	.....	4.	3.46	46.1	Sulphide.
	Hauerite.....	Iron black.....	Black.....	2-2.5	4.8	48.6	Oxide.
	Pyrolusite.....	Greenish black to black.....	.....	5-6.	4-4.4	63.2	
	Pailomelane.....	Brownish black to black.....	.....	1-6.	3-4.	30-70.	Bog manganese. Bog iron ore.
	Triplite.....	Blackish brown.....	Yellowish gray.....	5-5.5	3.4-3.8	Ab't 30	
	Rhodocrosite.....	Rose red.....	.....	3.5-4.5	3.4-3.7	47.27	Found as gangue in Butte, Mont.
Mangan. el.	Millerite.....	Brass yellow to bronze.....	Lighter than mass.....	3-3.5	4.6-5.65	60.4	Capillary pyrites.
	Nicolite.....	Pale copper red.....	Pale brownish red.....	5-5.5	7.3-7.7	44.	Copper nickel.
	Platinum.....	Dark steel gray.....	.....	4-4.5	16-19.		Generally found in small grains.
	Platiridium.....	.....	.....	.....	.....	19.64	Contains 78.6% iridium.
	Silver.....	Blackish lead gray.....	.....	2.5-3.	10.1-11.1		Native—generally contains copper and other metals.
	Argentite.....	Black to cochineal red.....	Cochineal red.....	2-2.5	7.19-7.4	87.1	Silver glance. Sulphide of silver.
	Pyrrargyrite.....	Light purple to light red.....	Light red.....	2-2.4	5.4-5.66	69.8	Dark ruby silver.
	Proustite.....	Iron black.....	.....	2-2.5	6.27	65.5	Light ruby silver.
	Stephanite.....	Gray, green, blue.....	Lighter than mass.....	.....	.....	65.5	Brittle silver ore. Black silver.
	Cerargyrite.....	Asparagus to olive green.....	.....	.....	.....	75.3	Horn silver. Silver chloride.
Silver.	Embolite.....	Bright brass yellow.....	.....	.....	.....	33.25	"Plata verde."
	Iodite.....	Steel gray to iron black.....	Blackish.....	.....	4.3-4.6	46.	
	Stannite.....	Brown or black.....	Pale gray to brownish.....	6-7.	6.4-7.1	37.	Tin pyrites. Tin sulphide.
	Cassiterite.....	Tin white.....	.....	2-2.5	6.1-6.3	78.67	Stream tin.
	Tellurium.....	.....	.....	.....	.....		Native tellurium.
	Tellurite.....	.....	.....	.....	.....		Minute white or yellowish crystals.
	Telluride.....	.....	.....	.....	.....		
	Tellurite.....	.....	.....	.....	.....		
	Tellurite.....	.....	.....	.....	.....		
	Tellurite.....	.....	.....	.....	.....		

\*The comparative hardness of minerals can be judged from that of the following: Talc, 1; rock salt, 3; orthoclase, 6; quartz, 7; topaz, 8; diamond, 10.  
\*Where no color is given it will be the same as the mineral in the mass.

## MECHANICAL PROGRESS.

## Increased Use of Iron and Steel.

## The Great Industry of the Future.

The rapid increase in the multiplication of the purposes for which iron and steel are used and the extraordinary increase in the consumption of those metals is one of the marvels of the age, and naturally suggests the query whether this constantly increasing rate of consumption will continue. That such will be the case is self-evident, and such increase will be due to two principal causes, which are, and must for many years continue, in operation.

On the one hand, there is the tendency for the use of iron to spread among communities not using it at present to the same extent as it is being used by the more highly civilized nations of the world; and, on the other hand, there is the ever-widening circle of purposes to which iron in one form or another is being applied. So far as the former cause is concerned, we may refer to the rapid growth which has taken place in the consumption in India and many other localities of late years; and as regards the latter, there are two cases in point. Firstly, the application of iron to shipbuilding purposes has extended so rapidly that, within little more than 30 years, the quantity thus applied has, in Great Britain, at least, come to exceed the tonnage of metal necessary for extensions of railways or renewals of permanent way. Secondly, there is the much more recent application of steel to the manufacture of railway sleepers, an application which is indeed only in its infancy as yet. In what other new directions iron may come to be employed in the future, it is impossible to say, but, with the experience of the past to guide us, it may with safety be predicted that finality has by no means been reached.

In regard to the prospect of the future demand by those which are at present non-commercial countries, an English cotemporary says: It has been calculated recently that 410,000,000 of the inhabitants of the globe consumed nineteen-twentieths of all the iron produced, whereas the remaining one-twentieth sufficed for the wants of 1,014,000,000 inhabitants. In other words, the latter consumed only 1.96 lbs. per head per annum, while the 410,000,000 used 107.57 lbs. per head. If, however, the 1,014,000,000 were to increase their consumption to a little over 6 lbs. per head—a very modest allowance compared with what the rest of the inhabitants of the earth require—there would be a new demand created which would necessitate the production of 2,000,000 tons more of iron every year. The possibilities of the future are, therefore, almost unlimited, for it will readily be understood that such an increase would not stand alone, but would, in the nature of things, occasion an increase in the rate of consumption among the 410,000,000 inhabitants.

These figures are highly suggestive, and lead naturally to the important inquiry as to what are to be the future facilities of this country for enjoying a share of this immense industry. The three main elements which have to be considered before an answer can be given to this question are as follows: First, the possession, in suitable proximity, of abundant and easily-wrought supplies of the raw materials. Secondly, the command of cheap and efficient labor. This latter has a very important bearing, seeing in what a peculiar degree the expense of labor enters into the cost of the manufacture of iron. Thirdly, the facilities enjoyed for the distribution of the finished product of the works.

With regard to the first we occupy as favorable a condition as any other people on the globe. In regard to the second we will have to rely largely upon the superiority of our skilled workmen, as the labor element here is inclined to exact larger pay than is required of our European competitors. It is possible that in the future, as it does now to some extent, well-paid labor may result in greater manufacturing skill and a more general use of machinery. It is possible that these two elements may more than counterbalance the uneducated cheap labor of Europe. Much in this regard will depend upon the laborers themselves. The facilities for distribution are not now what they should be; but a liberal and enlightened statesmanship ought to and might produce facilities in this direction equal to those possessed by any other people. This subject affords much matter for speculation, and should elicit the most profound thought of such of our statesmen as take any interest in the future growth of American industries.

**PULSATING BOILERS.**—We sometimes hear of "pulsating boilers." There is often a slight tremor in a boiler that might be called pulsation, but such phenomena are usually due to the pulsation of the steam pipe, which always takes place, to a greater or less extent, when the pipe is short and very rigid. Under such circumstances it often has the effect of shaking the boiler. Whenever there is a right angle turn there will be a thrust of the pipe in the direction opposite to the flow of the steam.

**WEARING OF WAGON TIRES.**—Country wagon tires wear in a curious way. If used much on a stony road they wear rounding, on clay, flat, and in the sand, concave. Tires much used in the Honey Lake valley wear in grooves. There will be a ridge in the center of the tire and a groove on each side, with the edge as high as the center ridge.

**SIMPLE TEST FOR THE CUTTING OF FILES.**—The Waverly Works, Sheffield, in a circular just issued, describe a novel and simple method which may be adopted by any workman to ascertain if files are machine or hand cut. Of course, it is an accepted fact that hand-cut files are capable of standing the most wear, and are in request by all workmen who have acquired the knowledge here described. With a straight edge, mark the angle of slope of the first cut on the file near the point, and again near the handle end of the file. If the teeth run in exact parallel, the file is machine-cut. In cutting with the machine, the angle at which the chisel starts is maintained throughout the length of the file, and the cuts must, in consequence, be parallel; whereas in handwork the hand of the workman, moving radially with the wrist as a center, necessitates a slight deviation from the exact parallel in every tooth, creating a considerable divergence in the angle of slope on the length of an ordinary file. This divergence may be seen by the eye on a large rough file, but it is difficult of detection on a narrow-pointed flat file; still, it will be easily apparent by extending the length of the lines with two straight edges. If the lines do not run parallel, the lengthening of the lines will at once show the divergence. The foregoing rule only applies to the first, and not to the finishing cut, as the man's wrist works quite differently in this cut. If the latter has been done by machine, this can readily be detected by observing that the first few strokes at the point of the file will be of the same pitch of tooth as farther up in the file; whereas the hand cutter for the first few strokes does not strike so heavily, but, so to speak, feels his way gradually, and consequently makes finer teeth than when he gets higher up into the body of the file. Some files are machine-cut at the point and finished by hand. By testing by both methods absolute certainty can be obtained.

**EXPERIMENTS WITH GIRDERS.**—In some carefully conducted experiments by the German government on steel and iron girders, each of the steel girders was found to show a large increase in strength over the iron girder, the soft steel girder proving 22 per cent stronger, and the hard steel girder 66 per cent stronger than the iron girder; the greater strength of the soft steel over the iron in the specimens was fully attained, and exceeded, in the girders, while the hard steel girders did not show so large a percentage of greater strength over the iron girder as did this material in the specimen. This last-named fact was accounted as the result of punched holes, which gave way by the fracture of the tension flange, whereas the girder with reamed holes gave way in the compression flange, and probably would have stood more before fracture had taken place in tension flange. Punching rivet holes without reaming did not produce any result other than an apparent loss of strength as compared with reamed holes. Lastly, the strength of steel girders strained in the manner of these girders appeared, by these tests, to be about the same for the two flanges, if made alike in sections.

**THE CORROSION OF BOILERS.**—M. M. Klein and A. Berg have been studying the action of sugars on the corrosion of boilers, and find that sugar in water has an acid reaction on iron which dissolves it, with a disengagement of hydrogen. The quantity of iron dissolved increases with the proportion of sugar in the water. The salt of iron formed is the acetate. A neutral decoction of malt also corrodes iron with disengagement of hydrogen; but glycerine and mannite are without action on the metal. These results are worthy of note in sugar refineries, and places where sugar sometimes finds its way into the boilers by means of the water supplied. The experimenters in question also find that zinc is strangely attacked by sugar; copper, tin, lead and aluminum are not attacked.

**BRAZING IRON PIPE.**—It is a very difficult matter for even an expert to braise iron pipe that has been split. It is much cheaper, says the *Scientific American*, to use new pipe. The brazing is done by cleaning the split edges, covering with borax that has been ground on a stone with water, and binding a piece of brass wire along the seam, with small iron wire wound around the pipe. Place the pipe in a charcoal fire, commencing at one end of the split, drawing the pipe through the fire as the brass melts. Soldering is done with a copper, using soldering acid, which is made by dissolving zinc in muriatic acid and adding a little sal ammoniac to the solution.

**WEIGHT OF GEARING.**—It is sometimes said that heavy gears run steadier and easier than light gears. Such is not always the case. Gearing should be heavy enough to do its work without strain or unnecessary wear upon cogs. Too heavy gearing is a detriment, and, moreover, to have the heaviest gears in the upper story of a mill or shop is reversing all mechanical laws as applied to the transmission of power, and displays a millwright's ignorance.

**A NEW MACHINE.**—It takes workmen well up in the use of the jack-knife to cut a lock in a hoop for a barrel, and it is a piece of work that was never supposed to be accomplished by machinery; but machines have been improved till at last it only requires the movement of a foot treadle and the three-way-under-gap is completed.

## SCIENTIFIC PROGRESS.

## The Flow of Metals.

## Properties Common to Fluids and Solid Metals.

In one of his recent lectures in London, Prof. Chandler Roberts-Austen spoke of the eight prominent points of resemblance between metals and fluids which have long been known. These eight points are the rejection of impurities on solidification, suffusion, flow under pressure, changes due to compression, absorption of gases, absorption of liquids, vaporization, and surface tension. Of these properties perhaps the most astonishing are those exhibited by metals when compressed. Placing cold powdered metals in a powerful press, Prof. W. Spring, of Siegen, caused lead to weld into a solid mass by a pressure of 13 tons per square inch; zinc, by 19 tons; tin, 32 tons; antimony, 38 tons; aluminum, 38 tons; bismuth, 38 tons; copper, 38 tons. At 33 tons per square inch lead actually begins to flow, and at 47 tons tin showed the same phenomenon. When a pressure of more than 50 tons to the square inch was given, the metals under experiment flowed through the fine cracks of the compression chamber like so much treacle. Prof. Spring also proved that the crystalline structure of metals may be changed by pressure as by fusion, and that it is possible even to build up alloys by pressure.

Prof. Austen pointed out that, although the characteristics of solid metals and of fluids appear at first sight to be widely different, there is much experimental evidence showing that under certain conditions solid metals behave like fluids. The phenomena attending the passage of metals from the fluid to the solid state were first dealt with, and the beautiful experiment of Van Riemsdijk, showing that pure gold, on freezing, behaved like water—that is, may be cooled below its solidifying point without becoming solid. When, however, by agitation, the metal sets, it becomes brilliantly luminous, owing to the liberation of the latent heat of fusion.

Passing to solid metals, Professor Roberts-Austen referred to a forgotten experiment made by Louis Lemery in 1726, showing that lead when cast in a peculiar form is sharply sonorous, and he alluded to Reaumur's experiments on this subject, which proved that hammering or the transfer of matter from one position to another by flow alters the shape of the grains and the way in which they touch one another, and leaves them, in the hammered lead, no longer free to vibrate. The results obtained by the late M. Tresca on the flow of solid metals were then fully dealt with, and the lecturer passed again to the elaborate investigations of Prof. W. Spring, on the compression of finely-divided metals into solid blocks. He repeated many of M. Spring's experiments, obtaining crystalline bismuth under a pressure of 6000 atmospheres, and building up the alloy fusible metal, which fused at 100° C. from the powders of its constituent metals, which have much higher melting points. The importance of the recognition of the flow of metals in science, in art and in industry was then referred to, and some observations by Mr. Baker, the engineer of the Forth Bridge, were alluded to as showing the important and beneficial effect of compression on the mechanical properties of steel destined to be used for certain purposes. Professor Austen concluded by showing that, as regards absorption of gas, diffusion, vaporization and surface tension, solid metals present close analogies to fluids.

**FINE DRAWN WIRE.**—Platinum wire has been drawn so fine by H. F. Read, of Brooklyn, N. Y., as to be invisible to the naked eye, although its presence upon a perfectly white card could be detected by the touch, and could be seen by the aid of a small magnifying glass when the card was held in such a position that the wire cast a shadow. A small platinum wire, about No. 18, was inclosed in a close-fitting tube of silver. The tube was made by taking a long and narrow sheet of silver, about one-twentieth of an inch thick, folding it over into a cylinder, and drawing down until the wire would just fit in it. This was then drawn down until the tube containing the wire was only as large as the original wire. A short length of this was cut off and incased in a second tube of silver, which was drawn down in the same way. This operation was repeated until the platinum wire had been reduced sufficiently in diameter. The last wire was drawn as fine as the dies would permit, when the silver coating was removed by an acid. During the work it was necessary occasionally to anneal the wire. It was designed to be used for cross wires in telescopes, its opacity and fineness rendering it particularly applicable, but its extreme weakness made its handling almost an impossibility.

**THE EFFECT OF LIGHTNING STROKE.**—An examination of the body of John W. Wilson, who was killed by lightning at Seymour, Ind., recently, showed a curious state of things. He was pumping water when a ball of fire leaped from a lightning-rod near by, struck him on the arm and burned several seconds. He did not fall and friends ran to his assistance, but he lived only five minutes. The bones of his arm were found to be shattered into countless fragments and the flesh was bruised and torn, but no other injury to his person could be discovered.

**LIABILITIES OF HOT AIR AND HOT STEAM.**—The subject of the spontaneous combustion of wood has been discussed at various times by the French Academy of Sciences. Among the most interesting statements made on these occasions is that by M. Cosson, describing an accident which occurred in his laboratory, it appearing that, while he was working in his laboratory, a portion of the boarding of the floor spontaneously took fire; the boards were in the vicinity of an airhole, fed with warm air from a stove about 13 feet away on the floor below. A similar accident had occurred two years previously, and, in consequence, M. Cosson had the boards adjoining the airhole replaced by a slab of marble. The boards which subsequently ignited adjoined the marble, and though the heat to which the boards were subjected was very moderate, being only that of air at 77° F., still the boards slowly carbonized, and, being thus rendered extremely porous, a rapid absorption of the oxygen of the atmosphere had resulted, and sufficient heat was thus produced to originate combustion. A similar instance of spontaneous fire is said to have occurred at Passy a few days before, due to the action of the warmth from the airhole of a stove upon the woodwork, thus showing the danger liable to arise from this source, and the necessity of attention to the same on the part of builders.

**INTERIOR TEMPERATURE OF THE EARTH.**—The *London Times*, referring to the deep shaft being sunk near Schladebach by the German Government, with the special object of obtaining reliable data concerning the rate of the earth's increased temperature toward the interior, concludes, from all that has thus far been developed, that the earth's crust cannot be more than about one-ninetieth of its radius. It seems that the plan pursued has been to ascertain the temperature at successive stages by means of a special thermometer, the principle of construction being that as the heat increases the mercury will expand so as to flow over the lip of an open tube, the difference of the overflowing giving the rate of increase of the temperature. At the depth of 1392 metres the temperature indicated 49 degrees Centigrade, or 120 degrees Fahr. If the temperature increases regularly at this rate, the boiling point of water ought to be reached at a depth of 3000 metres, or nearly two miles, and at 45 miles the heat would be that at which platinum melts.

**THE SOLIDIFICATION OF OXYGEN.**—Professor Dewar has succeeded in the production of solid oxygen. At the Royal Institution he lately exhibited for the first time to a few friends the method he employs. Last year the professor gave a lecture on liquid air; but, although he and other experimenters had made liquid oxygen in small quantity, no one had succeeded in getting oxygen into a solid condition. The successful device employed at the Royal Institution depends upon allowing liquid oxygen to expand into a partial vacuum, when the enormous absorption of heat which accompanies the expansion results in the production of the solid substance. Oxygen in this condition resembles snow in appearance and has a temperature of 200° C. below the freezing point of water. A supply of this material will enable chemists to approach the absolute zero of temperature and to investigate many interesting changes in the physical properties of bodies under the primordial condition of the temperature of space.

**HEAT OF THE GULF STREAM.**—It is well understood that Great Britain and other parts of Northwestern Europe owe much to the warming influence of the Gulf Stream. The extent of the effect has been given in the calculations of Dr. James Croll, who has found that the amount of heat conveyed northward in the Atlantic by this stream is equivalent to 77,479,650,000,000,000 foot pounds of energy per day, which is equal to all the heat received by 1,560,935 square miles at the equator, and more heat than conveyed by all the air currents. The heat of the Arctic Seas and North Atlantic would be diminished that much by the stoppage or diversion of the great ocean river.

Heat only flows down the gradient of temperature, and in any particular substance the rate at which heat flows is proportional to the gradient of temperature. Hence to get the heat from the source or furnace into the working substance a certain time must be consumed, and this time diminishes as the difference of temperature of the furnace and the working substance increases.

**THE PETALS OF THE BUTTERCUP** have, as well known, peculiar varnish-like luster. The cause of this has been investigated by Dr. Mobius, who attributes it to a highly refractive yellow oil existing in the epidermic cells, increased by the fact that the layer of cells of the mesophyll is densely filled with minute starch grains.

**SUBTERRANEAN HEAT.**—From his studies of the Krakatoa catastrophe, Verbeek is led to maintain that part of our globe remains still in a molten state, and he disputes the theory which has been advanced, that the heat of the volcanic furnaces is entirely due to the local chemical action.

**INSOLUBLE GLUE.**—In order to render glue insoluble in water, it is only necessary to add a little potassium bi-chromate to the water in which it is dissolved and expose the glued part to the light. One-fiftieth part of the bi-chromate will suffice.

## ENGINEERING NOTES.

## Substitutes for Steam.

At the recent spring session of the American Society of Mechanical Engineers, at Chicago, one of the most interesting papers presented was that by Mr. Geo. H. Babcock, of New York, on "Substitutes for Steam."

Mr. Babcock gave a brief history of many attempts to work engines by using some other fluid than steam, and said none of them had proved successful except air and gas engines for lighter powers. After describing the many attempts in detail and their failure, he reached the conclusion that a successful substitute for steam in motive power cannot be found among vapors, and most probably, if found at all, it must be among permanent gases. By a bountiful provision of nature an equally free and exhaustless supply of a perfect gas—atmospheric air—has been provided, which has several elements of value in the problem. As it requires 500° of heat to double its pressure at 39° Fah.—the point of greatest density of water—it may be heated to a very high temperature before it reaches a practical limit of pressure. It is a poor conductor of heat and does not condense when cooled; therefore, it will suffer less loss from being used in a cool cylinder.

Being a supporter of combustion, the fuel may be burned within the working fluid, and the loss due to the furnace avoided. It also offers the opportunity of recovering a larger share of its rejected heat to be used again. In a steam engine the only use to which this rejected heat can be put is in heating the feed-water and air for combustion, and only a small fraction—not over one-sixth—can be utilized in that way, while with air Rankine estimates that as much as 90 per cent of the heat in the exhaust may be retained for use, by a device invented by Stirling, known as the "economizer" or "regenerator." There are disadvantages, however, peculiar to air, among which are its bulk and the necessity of initiating motion by external power. The former is overcome by compression before heating, and the latter may yet be provided for in some simple manner.

Air, then, gives the best promise for an economical substitute for steam in pressure engines. The development of its advantages involves many difficulties, but these are fast being overcome. The air engine of Stirling of 40 years ago equaled in economy any steam engine of its day, while the Shaw air engine, of 1867, equaled in economy of fuel the largest and most perfect steam engines of to-day.

The Otto gas engine, and others of similar character, exhibit an economy of heat double that of our first-class steam engines, but they are handicapped by the necessity of using a very expensive fuel, and are necessarily confined to small powers and special circumstances. The prospect of much further economy in steam engines is not bright. By means of a non-conducting lining for the cylinder, a saving might be effected of, say, two per cent in fuel, bringing the efficiency up to 13 or 14 per cent, and by running the pressure up to 250 pounds we might attain, possibly, an efficiency of 17 per cent, or the same as is now attained in gas engines.

Are there still further possibilities of economical development of power? Probably not in the line of pressure engines. But science already points to the possible conversion of heat directly into electricity, and if that can be done without too great a loss the electrical engine may yet become a prominent rival of the steam or air engine. The conversion of 90 per cent of electrical energy into mechanical work is not beyond reasonable expectations, even if it is beyond present attainment, and if the heat of combustion can be converted into electricity with a loss of only 10 per cent—which is supposable—we then should get a horse power for .22 of a pound of coal per hour. This would be a saving of 30 per cent over the best probable results with air engines, or 85 per cent over the best results yet attained with steam.

Is steam, therefore, doomed to be superseded? By no means. Even if robbed of its position on the throne of power, it must ever remain one of the most useful servants of man. Its large specific and latent heat renders it the best attainable medium of transferring heat within a certain range of temperature, from the furnace to the place where it may be wanted for various processes, and even now it fills a larger field in that direction than it does as a prime mover. So far as now appears, it need fear no successful substitute in that field.

THE STATEN ISLAND BRIDGE, it is thought, will lessen the terminal charges in New York harbor about 25 per cent on all Western and Southern produce, by rendering available ten miles of water front in New York harbor, now inaccessible by railway. It is also thought that a revolution impends in regard to the shipment and storage of grain, flour, cotton and provisions of a very significant character for the West and South.

SWIFT STEAMER.—Efforts have recently been made in Europe to invent small steam craft capable of being propelled at almost express railway train speed. A small vessel for service in the Adriatic is now being constructed by a Prague engineer, the speed of which will, it is alleged, equal that of a fast railway train. This result is expected from an improved screw and a novel method of construction.

## USEFUL INFORMATION.

## Building Stone Should be Seasoned.

An important consideration in the use of stone for expensive buildings is that of having it quarried, stored and seasoned for some considerable time before being hewed, or at least before being placed in the walls. By these means the water naturally contained in the stone is allowed to evaporate and the stone is tested as to its quality. On breaking open a piece of the hardest granite or quartz that has just been extracted from a point in the earth below the permanent water-line—and often from much above that line—the severed walls will be found to be completely saturated with water, and in quantity sufficient to moisten the hand or saturate a handkerchief. Seasoning adds to the cost, but the money so expended is well spent in preventing the otherwise rapid wasting away of the stone from rains, frost or other atmospheric influences, which last, especially in cities, soon acts upon the surface of newly quarried stone.

Stone that is quarried one day and built into a wall the next day is in a green state and unfit for durability. It is at its weakest point of endurance either of pressure or of atmospheric influences. Its pores are open and ready to absorb not only moisture, but all the gaseous and disfiguring influences which tend to its destruction. Every stone mason knows that to get a polished surface on a stone the same must have lain for some time out of the quarry and exposed to the drying influences of the sun and weather. This is a sufficient hint to the builder to see to it that the stone of which he would rear a permanent structure must be thoroughly seasoned before it is placed into a wall.

A USEFUL LIGHT.—What promises to be a useful light for industrial purposes, where work has to be carried on in the open or large covered spaces by night, is described by the *English Steam Users' Journal*. The light consists of a cylindrical vessel capable of containing 30 gallons of heavy hydro-carbon oil. Air under a moderate pressure is conducted to the cylinder, which is fitted with a special burner having two tubes, one within the other, leading up to it. The inner tube dips into the creosote and the pressure of air on the latter forces it up to the tube. A portion of the air finds its way to the burner through the annular space between the inner and outer tubes, and the air and oil, combining at the burner, form, when ignited by a match, a flame which gives a light that is useful for general working purposes over a radius of 150 to 200 yards. The proportions used to form the proper light are four of air to one of oil by volume. The jet being produced under pressure, is not affected either by wind or rain.

HOW TO PREVENT GREEN SLIME IN TANKS.—Some one asks how to prevent green slime from collecting on inside walls of a water tank. My tank for several years was troubled the same way and had to be frequently cleaned, and at length I chanced upon what seems, after two years, to be the remedy. It is forcing air through the water. At first the feed-pipe to the tank discharged upon the surface of the water and there was very little disturbance. Then the pipe was changed so as to enter the tank at the bottom, and as the windmill is on slightly higher ground than the tank, the forcing in of the water by the pump carries with it a large amount of air, so that when the tank is filled it boils and bubbles at a great rate. Since that time the tank has been perfectly free from slime, and after two years has not required to be cleaned even once, and a colony of brook fish have kept it free from "wrigglers" of all sorts, and seem to have made fair growth, though fed very unfrequently.—*Country Gentleman*.

CATCHING FISH BY MACHINERY.—A Mr. Robertson, of Stockton, Me., owns a patent on a machine for catching fish, and is having a number of them made in Belfast. The implement consists of a frame on which is mounted a windlass which is geared to a strong spiral spring. The fish-line is wound on the windlass, and leads over a sheave at the end of an arm which extends out-board, and then to the water. The spring being wound up and the line run out, the machine is ready for operation. When the fish bites the pull on the line disengages the spring, and the fish, if he isn't stronger than the machine, is pulled in. When the sinker reaches the end of the arm, a catch which has held the arm in place disengages, and the fish is thrown in-board, and landed on deck. The model works well on land, and the inventor claims that he has given it a practical trial in catching haddock in the bay, and that it works perfectly.

NEW ZEALAND FUNGUS.—A curious trade has sprung up of late years in a peculiar kind of fungus that grows on the trees in the North Island of New Zealand, and which is exported exclusively to China. The uses to which it is applied do not seem to be well known. In 1873 the British authorities at Hongkong said it was "much prized by the Chinese community as a medicine administered in the shape of a decoction to purify the blood, and was also used on fast days with a mixture of vermicelli and bean-curd instead of animal food." Subsequent information shows that it is used in soups as ordinary food, and it is also used as a dye. The

exports during the past ten years have grown from £1927 to £18,939, but the increase has not been uniform. The gathering of the fungus is probably one of the vagabond industries; if so, the irregularity is easily accounted for. The exports in 1884 were 6387 cwt., valued at £11,079.

COLORING MATTER FROM THE COTTON PLANT. The value of the cotton plant (*Gossypium herbaceum*), great as it is, seems to have the possibility of being increased, since it has been discovered that the bark of the root contains an available coloring matter. W. C. Stahl reports that with alcohol of 0.84 specific gravity a red-brown solution is obtained from this bark, which, after distilling the alcohol, leaves a resinous residue, the weight of which is eight per cent of the bark used. This product has a black and shiny appearance, and, if pulverized, takes the color of cochineal. It dissolves in 14 parts alcohol, 15 parts chloroform and 122 parts benzol. It also dissolves in commercial alkalies and is precipitated by acid. With potash it becomes green, and sulphurous acid gives it a red-brown appearance.

PORPOISE FISHING is becoming quite an important industry on the Atlantic Coast. Quite a large number of small vessels are now engaged in the business, which is proving quite remunerative. A large factory has lately been established at Hatteras, N. C., for reducing these fish to their proper economical conditions. They yield a large amount of valuable oil; their hide is manufactured into a leather, valuable for many light but useful purposes; what remains is worked up for fertilizing purposes. They are caught in peculiarly constructed and very strong nets. Sometimes as many as 80 or more of these large and powerful marine animals—some of them fully eight feet long—are caught at a single haul. Some portions of the flesh are considered very good for food.

FRUIT TREES AND VINES.—The estimated number of fruit trees in this State is as follows: Total number of trees, 8,000,000, divided as follows: apple, 2,700,000; peach, 1,200,000; pear, 500,000; plum and prune, 600,000; cherry, 400,000; apricot, 500,000; orange, 1,600,000; lime and lemon, 500,000; grape vines in bearing condition, 70,000 acres.

BEESWAX.—Beeswax is nothing more than the voluntary excretion of the honey bee, like perspiration from the human body. To save time and to enable them to devote all their energies to honest gathering, apiarists now provide these bees with artificial comb, which the latter as readily undertake to fill as though constructed by themselves.

ALUM FOR SETTLING WATER.—It is said that a tablespoonful of powdered alum, sprinkled into a hoghead of water and stirred, will, in the course of a few hours, precipitate to the bottom all the impure particles and leave the water clear and pure as spring water. Four gallons would need but a teaspoonful.

## GOOD HEALTH.

## Interesting to Beer-drinkers.

A Petaluma correspondent of a cotemporary writes on the subject of beer-drinking and beer manufacture as follows: To begin with, there is not one quart of the manufacture of our breweries in this State that ever reaches the dignified state of beer. The patrons and the manufacturers alike are in too big a hurry for that. It is all drunk as sour mash. Let us explain.

Fermentation is the work of an infusorial cryptogam or bacteria. These little creatures make our alcohol in a struggle for existence. They are so small that billions of them occupy a space of half an inch, and in point of multiplication one will develop a million in 24 hours, while one hour is their average life. You must understand that they are a sexless animal. Should the beer-drinker, as a preliminary measure, place his delicate, foamy luxury under a magnifying power of eight or ten thousand diameters he would perhaps postpone the enjoyment of his delicacy to some future time. A vat of barley, undisturbed, might remain until it rotted and it would produce no beer. But stir it up and force the bacteria down in the fluid where they cannot obtain a sufficiency of oxygen upon which to live, they take the sugar and manufacture alcohol from it, and from the alcohol they can abstract enough oxygen to support life.

This is fermentation; but the fermentative process is only in its incipency before all the stuff is drunk. The foam on your glass of mash is cryptogamic. Drink it, and you convert your stomach into a vat for the fermentative process. The temperature of the stomach being favorable to their healthiest existence, fermentation continues, developing and disengaging a gas, bloating, weakening and relaxing the intestinal tract; impairing the digestive process, developing an alarming quantity of abnormal fat, weakening all the vital organs, and, finally, with an aldermanic corporeity, the victim steps down and out. And this is a subject that some medical men treat with levity. Thus far, we have not discussed beer, ale, or porter—simply the primary or elementary principle, sour mash.

When this mash has been bottled or bar-

reled from two years and nine months to three years it becomes beer, ale or porter, as the case may be. Then it becomes capable of imparting whatever benefits a stimulant may be capable of accomplishing, if any. But experience teaches that no stimulant is of any benefit except in actual indisposition, and under the same intelligent guidance that other therapeutic agents are prescribed. C.

Petaluma, June 15th.

## Bathing.

There are thousands of pores to each square inch of the skin of the higher animals. The office of these pores is to serve as outlets for the dead, offensive matter secreted by the glands of which they are the mouths. So much has been written about the offensive matter thrown off by the lungs and the contamination of the air thereby, that people are usually well informed as to the necessity for ventilation; yet the skin throws off, naturally, a greater amount of impurity than the lungs throw off. The skin and lungs throw off impurities in the relation of 11 to 7. But if the pores be closed, these impurities cannot be thrown off by the skin.

Whenever there is any check on this work of the skin, greater work is thrown on the lungs and kidneys; and this soon overtakes them; they are unable to accomplish all required of them, the blood becomes poisoned, and disease results. This has been demonstrated by Dr. Fourcault, who experimented in the suppression of the perspiration of animals. Just as the perspiration was interfered with were the evil effects manifested. The excretory action of the skin was entirely stopped by varnishing the animals; and this invariably produced speedy death. Any suppression of this action of the skin must produce a greater or less diseased condition of the body, since the blood can be kept pure only when the skin performs its functions properly. It has been well said that the great secret of preserving health is maintaining a healthy action of the organs that carry off the wastes of the system.

The matter exuded from the glands, of which the pores are the outlets, is of a sticky nature, and not only has it a tendency to adhere to the edges of the pores and close them, but it also holds the dust that falls upon it. In the summer the pores are closed most rapidly, because then the perspiration is most profuse, and there is the most dust in the atmosphere. The filth that clogs the pores can be removed most easily by the use of soap and water, or bathing. Hence bathing often enough to keep the pores open is essential; and it should be most frequent at this season. A house in the city is not considered complete without a bath-room; yet very few farmhouses have such a room, although farmers should bathe oftener, perhaps, than any other person.

The absence of bath-rooms in our houses shows our indifference to one of the most important methods of maintaining our health. The cost of a bath-room is but little, and every house should have one. But its lack is no excuse for not bathing. We can at least have a tub. And while we know that many of our readers will be incredulous when we say it, yet we know that the sounder sleep and greater bodily vigor attained through bathing makes it profitable ten-fold from a labor standpoint alone, not considering the gain in comfort and health. We know this because we speak from our own experience of years on the farm.

NEED OF COUNTRY SLEEP.—Some physiologists have said that three hours of close thinking are more exhausting to a man's vital energies than ten hours of the hardest physical labor. The nerves need building up and replenishing quite as much as the muscles. And they equally need rest, for recuperation. Men in literary employments, and in many kinds of business, especially in cities, are put to great mental strain during a few hours of the day. It is important to their health, to the maintenance of intellectual vigor and business efficiency, that their nervous systems have perfect quiet during at least one-third of every 24 hours. This cannot be had in a city residence. Though they may doze the usual period and their muscular powers be in a quiescent, semi-unconscious state, the nervous system is kept disturbed by the slightest noise, such as that of street cars, carriages passing on the pavement, of the early milk and market wagons, etc. There is scarcely ever any cessation of noise and jar in any city or large village, or at most during barely two or three of the small hours of the morning. The only absolute quiet to be found is in a country retreat, where wagons seldom move between sun and sun, and then only over soft earth roads which produce no jarring. Those business men are wise who retire every day in the year to a rural home, away from all disturbance. The writer has usually been in the midst of the city's hurry and scurry a part of each day for a third of a century; but the rule has been, when night came, to change the feet gear for dry covering that would be proof against any chill from damp ground, and then go for rest far from the city's turmoil. This course, with simple, digestible, nutritious food, has helped him to prolong his working power so that, though well past three-score, he is able to endure about as much daily mental labor as he could 20 or more years ago.

SALT FOR CORNS.—It is said that if common salt is placed upon corns on the feet and allowed to remain there for two weeks, the troublesome pests will come away without pain,

## MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

## CALIFORNIA.

## Amador.

**KENNEDY.**—*Amador Ledger*, July 2: Everything around this mine has suddenly assumed a beehive-like activity. The announcement that grading had commenced for the erection of a 40-stamp mill took the public by surprise. We are glad to be able to state that the report is true. Last Monday we visited the scene of operations and had an interview with the gentlemanly superintendent, Mr. Thomas. Some 30 men were busily engaged in grading. The spot selected for the mill is about 100 feet southeast of the hoisting works, lower down the gulch, with a fall of perhaps 30 feet between the two. The Fulton Iron Works of San Francisco has secured the contract for putting up the mill complete. Most of the heavy castings and other material are now ready, and will be shipped as soon as the grading is near completion. The stamps are to be 800 pounds in weight, and the mill will be finished with 16 Frue concentrators. The contractors guarantee it to crush 100 tons per day, and are under engagement to have it in running order by the 1st of September. It will be a first-class piece of work in every respect, equal, in fact, to any mill in the county. Concerning the prospects of the mine in justification of this movement for a new mill, we may state that there are large bodies of ore in all the levels, enough, in fact, to run a 40-stamp mill for five years. It is low-grade ore, and could not be made to pay under the expensive method of working in vogue 15 years ago. An examination of the books shows that the last 2000 tons of ore crushed yielded an average of over \$6 per ton in free gold. As the property was then fixed, running mill and mine by steam, and using 12 or 13 cords of wood per day, and crushing with 20 stamps of 400 pounds each, not more than 20 tons per day, it cost about \$16 per ton to mine and mill the rock, representing a loss of \$10 on every ton crushed. Work was prosecuted in the hope of encountering richer ore. Now, the calculation is to fix up in such a manner that this low-grade ore will yield a handsome margin of profit, and that this can be done in the favorable situation of the Kennedy for the use of water-power at hoisting works and mill, with 250 feet pressure, there is no room to doubt. The shaft is now over 900 feet deep. They are now making a sump, to be 45 feet deep. The sinking has followed the side of the ledge, and frequently the ledge would be exposed, showing ore of a richer character than that in the upper levels. It is intended to open a new level at 900 feet immediately. The prospect of the Kennedy taking its place among the permanent mines of the county is very flattering. As the ore body is large, it is estimated that mine and mill, when in full blast, can be run by a force of from 50 to 60 men.

**MISCELLANEOUS.**—The shaft of the New London, the rising mine of the Plymouth district, is now down nearly 400 feet, still in fine ore, with a tendency to pinch out. It is expected that the ore chimney will exhibit the same characteristics of narrowing and widening out at intervals as are met with at other places along the mineral belt, so that this pinching tendency is not regarded as a discouraging sign. The quartz is very similar in appearance to that met with in the Pacific. It is the intention of the company to sink to a depth of 800 or 1000 feet before anything will be done toward the erection of a mill. This company last week purchased another claim near the New London from A. B. Summers for \$5000. They are also working up a plan to get water to the property by the construction of a ditch to tap a large watershed in the mountains. The company means business, and everything indicates that it has unbounded confidence in the richness and permanence of its property.

## Calaveras.

**SALE.**—*Calaveras Prospect*, July 2: An important mining sale was made a few days ago in the disposal of the Esmeralda mine on Indian creek, generally known as the Kelly mine, to E. A. Davis. The former owners of the Kelly mine, Chas. Krause and Mrs. Kelly, had previously bonded the mine for \$500, and when the sale was consummated a cool \$10,000 in cash was paid down. Mrs. Kelly went down to San Francisco this week to deposit her money in the bank.

**MURPHYS.**—*Cor. Calaveras Citizen*, July 3: Mining matters are still stirring in this vicinity, and when the break in the Union Water Company's ditch is mended, work will be accelerated. Rock from two mines in Angels was hauled to the Oro Plata mill at this place to demonstrate the fact of superiority of the Tustin pulverizer over stamps in the mill used on the Utica, Chas. Lane, superintendent, and the pulverizer used by Col. Tozier in crushing his ore. The ore was passed through the Tustin, wet process, and was a triumph for the Tustin pulverizer. A number of mining and milling men were here several days to witness the result. Supt. Morse, of the Oro Plata, has added an improvement to the Frue concentrator, for which he has applied for a patent. It is a corrugated belt instead of the one now in use, and now one machine will do the work of three, and more thoroughly.

## El Dorado.

**RICH GRAVEL.**—*El Dorado Republican*, July 3: The bed of gravel recently struck in the Rogers mine, at Smith's Flat, holds its own both in volume and richness, and it is hoped it may extend into the ground of the Kum Fa mine, and reward the efforts of that company which is driving a drift in that direction. The Ohio mine, formerly known as the Valdora, at Grizzly Flat, has been bonded by the owner, A. H. McAfee, to J. H. Smith, the former superintendent of the Mt. Pleasant mine. Active work will soon be commenced on the mine. Under the direction of Mr. Smith, if there is anything in the mine it ought to be discovered. It has always been well thought of by miners. Joseph White, of Poverty Point, had a crushing of over 50 tons of rock run through the mill not long since which turned out \$5 per ton.

## Nevada.

**THE BADGER MINE.**—*Grass Valley Union*, July 2: All the water is now out of the Badger mine,

and after some work has been done, mining will be commenced. Another pump will be put in the old shaft, and the drifts cleaned out. An eight-inch ledge of fine-looking rock shows itself in the bottom workings. More will be known about the Badger in a few days.

**THE BUCKEYE MINE.**—*Transcript*, July 3: J. M. Kitts & Co., who are reopening the old Buckeye quartz mine at the junction of the Snow Mountain ditch and Slate creek, in Willow Valley, have recently struck a rich and evidently extensive chute of pay ore. The four-stamp mill which formerly stood on the Spargo mine is being put up on this one, and it will be in readiness to begin crushing this week. The Buckeye was prospected some several years ago, a tunnel 800 feet long being run. Kitts & Co. having cleared out the tunnel, are thus enabled to open and work the claim at a comparatively slight outlay.

## Placer.

**MAYFLOWER.**—*Cor. Placer Herald*, July 3: The Mayflower mine has shut down except work on the tunnel, which will be prosecuted under contract. The machinery for working Burleigh drills has been going through town for the past three or four days, for the Golden River mine near the Fork's house. They have already moved up the buildings from Succor Flat and will soon have everything in working order, and I hazard the prediction that they will develop one of the most extensive and valuable mines in the State. They are not investing their money at hap-hazard, but have called to their aid some of the most practical as well as the most scientific men in the State. The channel for which they are running is as well defined and known to them as though it was a living stream. If all the mining enterprises were carried on upon this principle, there would not be so many failures to record, such worthless waste of capital and labor to the detriment of our mining industries.

**MACHINERY.**—*Placer Republican*, July 7: The Golden River Company is having large quantities of machinery hauled by way of Forest Hill. An 8000-pound boiler was taken over by a four-horse team last week, which is thought to be the biggest load ever taken to that divide by four horses. The May Flower Company is hauling to the mine 24 tons of steel T rails for the new tunnel.

## San Bernardino.

**MINERS' WAGES.**—*Calico Print*, July 4: The large mining companies of East Calico recently reduced miners' wages to \$3 per day. Most probably the Oro Grande Company will be compelled to lower wages to the same figure, owing to the ore they are now mining being of a low grade.

## Shasta.

**AT WORK.**—*Shasta County Democrat*, July 1: Sunderhaus, Busch & Co. have 14 men at work on the Snyder mine, Squaw creek. Henry Herzinger left last Friday for a two months' prospecting trip in the Klamath range. B. B. Miner, a mining man well known in this county among the miners, died in Los Angeles last Thursday, of paralysis of the brain. Uncle Dick Johnson is prospecting in the Backbone country for some rich gold quartz he and his old friend Hoovy found in that region over 20 years ago. Thomas Derby, who a year ago had bonded the Whitton and Small mines on Squaw creek, now known as the Cresson mine, went up on the train last Monday evening to look at some mining property in that camp. We stated last week that De Forest and the Bemis Bros. are developing a piece of mining property at Lower Springs on the widow Myers' place. We erred as to De Forrest. The Bemis Bros. are doing the work, and have the property bonded.

## Sierra.

**EXTENSION.**—*Mt. Messenger*, July 3: The Bald Mt. Extension Co. have commenced pumping water at the Pliocene shaft for washing their gravel at Forest city. To dispel the misunderstanding occasioned last week by our item in regard to the Bald Mt. Extension drift mine, Forest City, we will state that the men employed there only were able to work two days, the previous week, owing to a cave in the breasts, and in that time there were taken out 350 carloads of gravel, yielding 95 ounces of coarse gold, over \$5 per carload. Mr. Vanslyke is progressing satisfactorily with his mining affairs. The pump at Butcher Ranch has been started and the shaft about drained. The main tunnel is advancing rapidly. The rock is soft, and the ledge will be struck about 150 feet ahead. Arrangements have been made with John Schriver, of Goodyear, to run his sawmill and furnish lumber for the Gold Valley quartz mines.

**MORE STAMPS.**—*Sierra Tribune*, July 3: Of the additional 20 stamps which are being put in at the Young America mill, ten will be ready for operation by July 5th. The other ten will be ready a few weeks later. When all of those stamps are turned loose (there will be 40 altogether) the Young America will by its big yields make this district famous in mining circles.

**NOTES.**—There is activity all along the line. The owners of the Perry Consolidated, across the river south of town, are crosscutting this week and are meeting with most excellent indications. We understand that the Loyalton parties are highly pleased with the prospects which they have encountered in their ledge at Gold Lake. Work has been resumed at Gold Valley, and it is believed that the improvements in machinery and knowledge of working ores will make a success of that property. The ore is said to assay very high, but most of the gold is in the sulphurets. Charley Hendel has six men at work on his new discovery and feels quite certain that he has a bonanza. At the Cleveland they are adding 10 more stamps to the mill, and the mine looks well enough to satisfy its owners. At the Young America mine, work on the mill addition is going rapidly ahead, and the 20 new stamps will be crushing before long. This company concentrate their mill tailings, and probably will erect chlorination works after awhile. No change of note is reported at the mine. The hills are full of prospectors, and nearly every day a party of them comes in town, gets a small bill of "grub," some tools, and goes out, no one knows where, to prosecute work on some new find. There is lots of gold left in Sierra county.

## Trinity.

**PAYING WELL.**—*Trinity Journal*, July 3: Bailey, Lawton & Bergin made a cleanup of their arastra on East Fork this week. Twenty tons of rock from

the Thanksgiving mine yielded at the rate of \$45 per ton.

## NEVADA.

## Washoe District.

**CHOLLAR.**—*Enterprise*, July 3: The station for the 3200 level, which is being opened out on the west side of the shaft, is a very roomy affair, being the whole width of the shaft, 30 feet, and it has been carried back for the same width a distance of 20 feet from the shaft. It is 11 or 12 feet in height, and is very heavily and substantially timbered, owing to the unreliable nature of the ground, the shaft and station being in the main ore channel at that point. The material has been largely quartz, most of which gave low assays, and, as heretofore stated, being in the ore channel itself, every foot of progress westward was very liable to crosscut into a good ore body at almost any time. Therefore the strike of Thursday night, when the face of the station suddenly cut into a well-defined ore vein, was not altogether unexpected. How valuable and extensive this new ore deposit is cannot be stated at present, as work has been suspended pending instructions from below. The miners, however, as well as all others concerned, consider the strike an important one, judging from the little they have seen of it, the good assays coming from it and the peculiarly fertile and "kindly" character and texture of the rock. Ore has never been found so far south by 300 feet in the deep explorations of the middle mines, and in connection with the huge ore vein adjoining and running to the southward through the Chollar and Potosi, the indications are that the ore is "growing" in the lower levels.

**HALE AND NORCROSS.**—On the 2900 level a diamond drill was sent out west from the face of crosscut No. 5, which demonstrated a strong ore vein in that direction, and the drillings also indicated good ore. Last Monday the drill was withdrawn, and since then the crosscut has been advanced, verifying the drillings by cutting through ore of a fair grade, with streaks and bunches of rich ore. A good strike is anticipated further in. The drill hole in the face of the main north lateral drift is allowing the water to drain out from that direction.

**SAYAGE.**—Work is suspended in the face of the main lateral drift south on the 600 level, owing to the swelling nature of the ground passed through necessitating the easing of the timbering and lagging. A drain is also being cut throughout the entire length of the drift to the Gould and Curry line. This will be properly boxed throughout, and is intended to drain the water met with in the face of the drift, and any increase of the same that may be encountered. It will also receive the drainage from the east crosscut. This crosscut east is being advanced, with its face in good-looking vein material—porphyry, quartz and clay.

**BEST AND BELCHER.**—At six o'clock A. M. yesterday, the raising of the flag over the hoisting works of the Osbiston shaft signified the fact that at last the water was drained out, and the track floor of the 2319 or bottom level reached. The station is now being cleaned out and repaired, and when all other requisite arrangements are completed, the proposed sinking the shaft deeper will be resumed. This present lowest level corresponds with the 2500 level of the C. and C. shaft. The Osbiston shaft is to be sunk 400 or 500 feet deeper, to correspond and connect with the 3200 level of the Combination shaft.

**CROWN POINT AND BELCHER.**—The main double hoisting engine at the Crown Point having been repaired and started into operation, the full force of miners were put to work in both mines on Tuesday, and about 400 tons of ore per day are now being extracted as before the break-down.

**ALTA.**—The west drift from the main north lateral drift on the 700 level, which was expected to intersect the Lady Washington shaft, is found to have passed it entirely, owing to an inaccurate survey. The face of the drift is now 175 feet west from the north lateral drift, and is being pushed forward to intersect the Keystone ledge, upon which the old Justice mine is located. About 125 feet further remains to be drifted to reach the Keystone.

**POTOSI.**—The diamond drill, which was being run to the eastward on the 3100 level, after penetrating 235 feet, had to be withdrawn, owing to the difficulty experienced in working it to such a great distance. About 200 feet of it is in a pure, solid vein of quartz, more or less mineralized throughout, and now the hole is being reamed out, to make it larger and allow the drill to be driven further in, and, if possible, to the other side of the immense vein.

**OPHIR.**—The surface machinery, which has been thoroughly overhauled and put into a complete state of repair, was started into full operation again day before yesterday, allowing of a full resumption of exploration and other work in the mine.

**GOULD AND CURRY.**—The crosscut west from the upraise incline, 50 feet above the 500 level, is still in good-looking vein matter, giving low assays. The same may be said of the east crosscut and the north lateral drift at that point.

**SIERRA NEVADA.**—On the 520 level the north lateral drift from the west crosscut was advanced 45 feet during the week, making a total of 215 feet. No change in material.

**CON. CALIFORNIA AND VIRGINIA.**—Daily yield about 400 tons, as usual. The exploration work on the 1400 and 1600 levels goes ahead judiciously, as usual.

**YELLOW JACKET.**—Daily yield 140 tons from the old stopes and breasts above the 1500 level.

**KENTUCK.**—Daily yield 60 tons from the old upper workings, keeping the Rock Point mill steadily supplied.

## Aurora District.

**RESIGNED.**—*Aurora Star*, July 5: We understand that Mr. Mills, the superintendent of the Con. Esmeralda Company, still acting, sent in his resignation as superintendent some days since. Considering the condition of the property, mines and mill, at the time he took charge, and what has been accomplished since by way of repairing the mill at a cost of \$12,000, and the development work on the Durand Middle Hill tunnel; the sinking and drifting on the New Esmeralda property; the work on the Esmeralda and sinking 200 feet of shaft at the Humboldt, crosscutting at the two and three hun-

dred foot levels and sinking the winzes between the 90 and 200-foot level, and some other work on other properties connected with the Con. Esmeralda Company, costing in the aggregate perhaps \$60,000, and in the meantime taking out ore to keep the 20-stamp mill running and producing bullion to pay a third of the expenditures—it may be said of him, "well done."

## Jackson District.

**MILL RUNNING.**—*Silver State*, July 2: Charley Bernard is in from Jackson District. He says that Pennsylvania mine is looking well and the mill is running steadily. The mill has ten stamps, four concentrators and two pans and a settler. All the base metals and sulphurets are saved by the concentrators, and the chlorides are amalgamated in the pans.

## Paradise District.

**ORE.**—*Silver State*, July 2: One of T. C. Emery's teams arrived yesterday with 16,581 pounds of concentrated ore from the Paradise valley reduction works. Yesterday E. Reinhart & Co. shipped a carload of concentrated ore from the Paradise Valley Co's mines to Argo, Colorado.

## Tuscarora District.

**NORTH BELLE ISLE.**—*Tuscarora Times-Review*, July 3: The crosscut on the 150-foot level, near the old shaft, has been extended 17 feet the past week. South drift on east vein from No. 4 crosscut, 350-foot level, has been extended seven feet and connected with the north drift from No. 5 crosscut, making good ventilation; south drift from No. 5 crosscut on the east vein, same level, has been extended eight feet. South drift on the west vein, 150-foot level, has been extended 12 feet. Have stopped work in No. 6 upraise on the east vein, same level, and started upraise No. 7, 75 feet further north on the same vein. Stopes on the 150 continue looking well. Mill running on company and custom ores.

## White Pine District.

**CLEANUP.**—*White Pine News*, July 3: J. R. Kendall, of the Jennie A. Co., is at present engaged in a general cleanup of the California mill and doing needed repairs on their water privileges, which are among the best in the county. Frank Paul, who has a lease of the Edgar mine, has four men at work, and himself and Oliver Whalen, lessees of the Eberhardt Company, have a like number at work on the North Aurora. Ore is being hoisted from both works, and a test is to be made of the values thereof. Assays from the latter are reported as showing up well. The water tunnel running as a connection between the Sweetwater Company's lower well and the upper one, across from Hayes, is being pushed on and has about reached the contract of 100 feet given Messrs. Pritchard and Lewis. They have worked eight-hour shifts latterly, as the ground became very hard and the water seriously interfered. The distance still to go will probably be contracted for shortly. S. E. Starrett, in a close, almost abandoned mine near town, by his indefatigable exertions, has struck a good showing, and may have found that which many have sought but failed to discover—a very rich pocket, as some have before been found in the same locality.

## ARIZONA.

**GLOBE DISTRICT.**—*Silver Belt*, July 3: The development of mines in Globe and contiguous districts has been greatly retarded by reason of the low price of copper and a lack of capital to systematically work our silver properties. Our nearness to the White Mountain reservation has also militated against the growth of the camp. However, if we read the signs of the times aright, the day of our prosperity is near at hand. With the construction of the Arizona Mineral Belt Railroad, our numerous rich deposits of copper ore can be profitably worked, and Eastern capital will seek investment with us. Globe has the resources to make it a mining center second to none in the Southwest.

**MORENCI.**—*Cor. Clifton Clarion*, June 30: Matters at Morenci are quiet. The regular force of men are at work and the output of copper up to the usual amount. A change has been made in the gearing of the concentrators, and the rate of speed has been changed. They are now working to the best advantage possible and the result is highly satisfactory. Mike Shea and Louis Jantzen are working their mine, the West Thompson, and are taking out some fine ore. The prospect for this mine is good.

**GOLD.**—Several parties are engaged in washing gold on the river near Oro with a fair measure of success. The gold exists in large quantities in the cement-like formation along the river, and if a system of hydraulic works were established, by which the gravel might be quickly and economically washed, with proper management the working of the claims along the Frisco might be made a financial success.

**LONGFELLOW.**—*Clifton Clarion*, June 30: Mining matters are quiet, the regular work going on as usual, with nothing startling or strange to report. Ore is being brought in from the Clay mine, and we presume will be run through the concentrators at the company's works, when those shall have been completed.

**QUEEN.**—Among the new prospects visited were the following claims: "Lizzie," the property of N. C. Hinds; "Lee," owned by J. H. McGuigan; "Rob Roy," J. H. Vaughn owner, and "Little Gem," belonging to Henry Hill. These are situated about five miles to the northwest of Clifton, in the range back of Chase creek, and all within the limits of the Greenlee Gold Mountain mining district. The claims promise well, and with proper work, no doubt, can be made to pay. The mountain on which they are located is covered with a good growth of evergreens valuable for fuel. Nothing is known as yet as to the extent of the mineral body on the leads, as no prospect work has been done; but apart from that, the four locations are valuable for the timber that is on them, and are well worth doing the legally-required assessment to acquire a title.

**NUCKET MILL.**—*Silver Belt*, July 3: J. C. Ogden will start up the Nugget mill, after the 5th, on ore from the Fame mine. There will be over 30 tons of high-grade ore and a considerable quantity of a lower grade. It is expected that the yield from this lot of ore will be much greater than from the last, which was in the neighborhood of \$11,000,

The Fame is now the largest silver-producer in Globe district, and is worked in a systematic and economical manner. The ore house is connected with the mine by a track through the main tunnel, which reduces the cost of handling the ore to a minimum. We are told that the mine never looked better than at present.

#### COLORADO.

**TUNNEL.**—La Plata Miner, July 3: Some weeks since the Miner gave notice that another tunnel would shortly be run under the workings of the North Star on Sultan, and the officers of the company are now here with a view of beginning the work right away. As the successful completion of this tunnel will require considerable engineering ingenuity, the gentleman who runs the 12,000-foot tunnel at the Big Bend in California, lately completed, has been sent for, but as the Big Bend Company have offered him extraordinary inducements to remain in their employ it is probable that the North Star people will have to look elsewhere for the man they want. The tunnel will be 2100 feet long, and it is estimated that the work can be completed in one year with the use of air drills, whereas two years will be required with hand power. Mr. L. B. Kendall, the president of the company, with surveyors, was laying off the line of the tunnel on Monday last, and he states that air drills will be used in the work and the tunnel pushed to completion. The work is to be commenced Monday. The depth gained under the present lower workings will be 190 feet, which is very small considering the length of tunnel to be run, but the tunnel will open up 3000 feet of ground, every foot of which contains pay ore, which could be run out of a tunnel much cheaper than it could be hoisted from a shaft. Only 60 feet above the creek level is allowed for dumping ground, which will be ample, and the tunnel will be large enough for a double track and for the admittance of machinery, when it shall be found necessary to continue exploitation below the tunnel level. An increased force is to be put in the upper workings and the output largely augmented, which is controlled by the number of men employed. The present output is 300 tons per month and the ore body in the stope is scarcely scratched. On the completion of the new tunnel the North Star will be one of the most extensive and best developed mines in the State.

#### IDAHO.

**BALD MOUNTAIN.**—Coeur d'Alene Record: Louis Block gives the Record some particulars about the quartz prospects up the east fork of Eagle creek. Beginning about 1800 feet from the foot of the mountain, six miles above Eagle city, is the Keystone, owned by Campbell, Pease & Rice; next, Buckeye, owned by Woodling, Coad, Dokey & Stoops; next Sandusky, owned by Coad, Woodling & Dokey; next Mountain Rose, owned by Block & Stoops; next Crown Point, owned by Block, Woodling, Dokey & Coad; next Emma, owned by same parties; next Clara, owned by Olendorf, K. S. Burke, Penny & Linn; next Belcher, owned by Block & Frank Olendorf. On another vein McAllister, Olendorf & Avery own the Chieftain; Rice, Campbell, Pease & Nagle, the Phoenix and Alice; McAllister, Morrill & Avery, the Grub Stake and Evergreen; Woodling, Coad & Doty, the Wyandotte; Block, Stoops, Vernon & Landes, the Vivian; Rice, Campbell, Pease & Merrill, the Silver Bell; Renkard, Peck & Crown, the Howling Dog and the Silent Friend. There has been some work done on all these locations, and all show free milling gold and silver bearing veins. Most of the work being done now is on the Mountain Rose, Crown Point, Emma, Clara and Belcher. The richest tests have been made from the Emma, reaching the astonishing figures of \$25,000 in gold to the ton, these assays being from decomposed mineral matter distributed through a two-foot vein at a depth of about 20 feet. The shaft on the Belcher is now about 25 feet deep, and the vein five feet wide, and improving in width and richness, assays reaching to \$500, though taken together it will probably run about \$25. Over the mountain the other side there are more locations and as much work as on the south side, and will be kept up all around till enough is done to establish the question of their true character.

**CLEANUP.**—Coeur d'Alene Record, June 26: We are informed that Mr. Herrman made a cleanup of about 300 ounces of gold from a pit at the head of the Trail gulch bedrock flume. The Coeur d'Alene Water Supply & Mining Company are making active preparations for more vigorous work on the flume commonly known as the Coulter ditch. Additional workmen will be put on at once and the force gradually increased as fast as profitable work can be done. Wm. M. Stoops came in from Bald Mountain to-day. He states that the mine-owners have just completed a good trail up to their claims some six miles from Eagle city. The prospects are all improving as work progresses. Frank Olendorf and Louis Block are down 16 feet on the Belcher and have a vein 5½ feet wide, making a gain of two feet in width from the start.

**AFTER QUARTZ.**—Idaho World, June 25: Deadwood Basin and Silver district promise to be the chief magnets this season for the prospectors. A large number of prospectors will flock into the former place soon from Custer county and other points. Fifteen or twenty locations were made there last fall by citizens of Custer county. Silver district already has quite a large number of newcomers, mostly from Atlanta. Both these districts will be thoroughly prospected this season for quartz. Matt, Graham, Sr., and Matt, Graham, Jr., we are informed, will soon have ore from their mine—the Julia—crushed in one of the Atlanta mills. George Bidwell came down a few days ago from near the head of the Thorn creek ditch, where he has been since the mining season opened, tending the said ditch. The Thorn Creek Ditch Company quit work last Tuesday. Their head of water weakened a few weeks earlier than last year.

#### MONTANA.

**THE CLEAR GRIT.**—Inter-Mountain, July 5: Operations on the Clear Grit are confined principally to the 220 and 320-foot levels and the intervening stopes. The first has a length of 160 feet east and 300 west of the shaft, while the second extends 60 feet east and 250 feet west of the shaft. On the

lower level in the face of the west drift the pay ore body has a width of six feet, the same as in the level above, while eastward it increases in size to the face of the east drift, where a 15-foot breast is being extracted. In the 220-foot level, at a point 150 feet west of the station, a cross vein intersects the main ledge. It carries a very high grade of ore, assaying on an average \$100 in silver, \$30 in gold and a percentage of copper. This cross vein is being followed in both directions from the point of intersection, and is yielding handsomely. The pay streak is about one foot wide. From the main workings the daily product is between 25 and 30 tons, assaying from 6 to 10 per cent copper and 25 ounces in silver. It is being treated at the Butte Reduction Works, where its character renders it particularly desirable for fluxing purposes, as it carries fully 70 per cent iron and only 30 per cent silica, with no zinc. Mr. Kessler is working 18 men on the property, and is naturally in high spirits over its magnificent appearance.

**NOTES.**—In the Gagnon, drifting west is progressing on the 600 level. The report of the bonding of the Nettie for \$150,000 is untrue. The Elm Orlu is producing 25 tons of ore daily.

**BEAVERHEAD MINES.**—Cor. Butte Inter-Mountain, June 25: A new steam Frazer & Chalmers hoist is being placed in position on the Rena, in the Argenta district, with a capacity of working to a depth of 400 feet. A new shaft is now down to a depth of 40 odd feet, the old one being so crooked as to be unfit for use. Three carloads of ore have been shipped from this mine and a fourth is now ready. The returns for those already sent give \$75 in gold, from \$15 to \$30 in silver, and a small percentage of lead. The Dexter property in the same district met with an accident which will seriously retard its development. Owing to the owners being busy developing other claims the Dexter was suffered to remain idle for a short time, during which it filled with water. A short time ago some parties from Butte came down, and getting a lease, started to revive work. The pumps were put in and started, and work was just fairly begun, when it was noticed to be unsafe. The utmost haste served only to get the machinery out of the mine, when it caved almost from the surface. The shaft was about 125 feet deep with numerous drifts upon the ore veins. It is expected a new shaft will be sunk right away, and the development of the mine continued. The last ore shipped from the Dexter was a sample lot of 80 sacks, which netted considerable over \$100 per sack. The Golden Era, belonging to French & Laughlin, is reported as a bigger and better thing than ever. Work is rapidly being pushed, and a great deal of ore extracted. The properties worked by Morgan & Grubb are turning out a high-grade ore. A sample lot of 8700 pounds netted \$157 per ton. The Bismark, owned by L. C. Fyhrle, is reported as having developed a wonderful amount of ore of great richness. Rumor says that a consolidation of the Kent and Bismark properties may be looked for and great improvements will be the result. B. C. Kingsbury, who returned from a tour of inspection of the mines in this region last Saturday, confirms the reports of the value of the Cavanaugh properties, one-half of which are owned by Mr. L. C. Fyhrle, and speaks in great praise of the mines of G. W. Perkins, which are situated away above timber line on Bald mountain. The properties of the Lillon Mining Company are reported by Mr. Connors as awaiting the finishing of the mill, which has been much delayed on account of the trouble to obtain lumber as fast as needed. Matters are now being rushed to completion, and we may soon look for splendid results. Placer mining along the bed of Grasshopper creek is actively progressing, with apparently the best of results. The Shelby Mining Company are still to the front in furnishing large quantities of high-grade magnetic iron ore from the mines on Birch creek, under the management of Mr. O. Willis. It finds a ready sale to the Hecla company, and some has even been shipped into the Wood River country with good results. The tin mines, just across in Madison county, being owned and operated by Dillon capital, deserve mention here. They are being actively developed and expect to make a showing soon that will astonish our people.

**AROUND HELENA.**—Helena Independent, June 28: The mining business of the district tributary to Helena is developing so rapidly that it is becoming recognized as one of our greatest and most profitable industries. The Independent learns that work on the Empire is progressing in the most satisfactory manner, and that the new mill will be completed about July 1st, the arrival of the machinery having been delayed by the labor troubles in the East.

#### NEW MEXICO.

**ORGAN MINES.**—Rio Grande Republican, July 5: Anthony Comstock and Billy Gibbs went to work on the Grey Eagle last week. Their labors were rewarded by finding a pocket of high-grade ore, the extent of which is not yet known. The mine has yielded well in the past and has a future before it. Not long ago the mine in the Organs known as the Poor Man's Friend was leased to a Mexican who got out 1200 pounds of poorly assorted ore and it was shipped to Socorro by Williams & Lohman. The returns on this shipment, after all expenses were deducted, netted the shipper \$26.28. The mine has now been leased to Barlen and the Foyes, who are getting out a ton a week of \$200 ore. S. M. Ashenfelter was in the city this week and completed arrangements with the Foy Bros. of Organ, leasing to them the old Stephenson mine which he jumped several years ago. It will be remembered that this property was patented, but Ashenfelter jumped it on the grounds that the company to which the patent was granted no longer existed. He now proposes to start work and go to shipping ore, tons of which are in sight, and thus force the other claimants to bring suit against him.

**ORE.**—Silver City Enterprise, June 26: J. B. Malone recently made another shipment of ore from the Tenderfoot mine which returned him 360 ounces per ton. The Tenderfoot will soon have a record as one of Grant county's best producers. Advice of the past few days from the Mogollons state that the new turbine wheel for the Peacock company has arrived and is being placed in position. The vanner floor of the mill is covered with concentrates, which are being sacked for shipment. W. C. Hadley, superintendent of the Lake Valley mines and mills, visited this city last week. He reports everything

about the mines and works as flourishing. The mill is now running on regular time and is saving the metal up to 90 per cent. Mr. Hadley is well satisfied with the success with which he has met as manager of the new plant. The enlargement of the ore body at the bottom of the Atlantic mine, Pinos Altos, has naturally resulted in an increased production of ore from that property. Not only this, but with the increase in size came an increase in the value of the ore yielded. Free wire gold is found quite frequently, and the average proportion of value saved under the stamps continues as high as before. The new ore body is fully 2½ feet in width along the bottom of the shaft, and drifts that have been started both ways on the vein show it to be continuous. An average of ten tons is now outputted daily, and this will shortly be more than doubled when stopes are started. Two carloads of concentrates were recently shipped by Messrs. Lewis & Perkins that assayed between \$70 and \$80 per ton. Some beautiful wire gold specimens are produced from the new ore body. The Bremen mill, with the many changes recently made, started up one week ago, and has run continuously since in a most satisfactory manner, treating 20 tons of ore daily, saving the mineral much more closely than during any time in the history of the mill. The new machinery came from the reliable old house of Fraser & Chalmers, Chicago, that furnishes nine-tenths of the legitimate mining companies of the Rocky Mountain country with plants that always give satisfaction. C. H. Wilkie superintended the construction of the machinery, while Frank Milstead has charge of the running of the mill. The amalgamating process works particularly satisfactory, as does every portion of the new plant. The mill is now one of the most complete in the Territory, and is doing work second to none.

#### OREGON.

**HAVE DONE WELL.**—Jacksonville Times, July 2: The miners of Grave, Wolf and Cayote creeks, Josephine county, have generally done well during the past season. Geo. H. Lynch and others, while engaged in running a ditch in the Wagner creek district, discovered two quartz ledges which promise well. We learn that Desselles & Connell, of Scotch gulch, have sold their well-known mining claim to a Chinese company for \$25,000. It is one of the best in the State. The Wagner creek quartz mill is running regularly now and crushing a considerable quantity of ore daily. Some more machinery will be put in before a cleanup is made. Ex-Governor Chadwick has some intentions of putting in a mill at his quartz ledge near Rogue river, and has had that stream examined with the intention of securing water-power. McDonough & Co. struck another small pocket in their ledge near Fort Lane, which yielded a neat sum of money. The Sterling Mining Co. are about bottoming up and will soon commence their annual cleanup. Their ditch is full, but as the snow at its source has melted the supply will soon begin to fail. Smith & Lynch, who purchased the diggings on Wagner creek in which S. McConnell found a \$300 slug last spring, have had a ditch surveyed to bring enough water to them to insure several months' run. It will be nearly three miles long. The miners of Foot's creek are cleaning up with favorable results. Most of them have done better this season than for several past. Shepherd Bros., who are working their ledge on Sugar Pine gulch, two miles south of Ashland, have had some rock tested and \$40 to the ton is reported. The placer miners of Southern Oregon have generally gone into summer quarters. Much more gold dust has been taken out during the past season than for several past. The Wagner Creek Mining Co.'s large new mill, in which Messrs. Koehler and Brandt, of the O. & C. R. R., are interested, will soon be grinding at its fullest capacity. Much faith is put in the mines of Wagner creek, and we hope to see it fully realized. Prospects at the Hope ledge on Wagner creek, owned by Messrs. Bragdon, High, Garret, Alford and others, are of a favorable nature. They have sunk a shaft 50 feet deep, where the ledge is over four feet wide and yields ore containing considerable free gold. Brown & Co.'s mill, in the vicinity of the Swinden ledge, is doing good work. The stamps purchased of N. DeLamater, of Kerbyville, are being used and prove much more satisfactory than the grinding apparatus heretofore utilized. There is said to be endless quantities of decomposed quartz, which is easily worked and pays well. Several hundred dollars have already been realized. Chas. Baume, of the U. S. bakery, has bought the machinery formerly used by Beekman & Klippel, and will add enough to it soon to make it a first-class ten-stamp mill. He has also purchased the old Bowden mill-site on Jackson creek, in which vicinity exist excellent mines, in some of which he is interested. It is expected that there will be enough ore on the dump to keep the mill running when it is completed, which will probably be in the course of a few months.

#### UTAH.

**REVIEW.**—Salt Lake Tribune, July 2: Bullion receipts in this city for the six months of 1886 were as follows: January, \$328,852.66; February, \$456,024.03; March, \$469,722.63; April, \$519,666.08; May, \$387,891.49; June, \$527,036.97; total, \$2,689,243.86. This excludes all ores, and reckons only the bullion and refined precious metal produced. The receipts of ore in this city for the week ending June 30th, inclusive, were \$58,575.57—a good average. Of bullion in the same time, the receipts were \$101,002.08—a total of \$160,178.55. For the previous week the total receipts were \$204,790.88, of which \$109,001.47 was bullion and \$95,789.41 was ore. No bullion came down from the Ontario during the week; the run of the silver stream has not begun since the cleanup at the mill. The ore sales for the week were two lots, of an aggregate value of \$17,003.34. The Daly product for the week was 16,511.36 fine ounces. Base bullion receipts for the week were \$17,950; one silver bar, \$150; fine bars, \$1300. The product of the Hanauer smelter for the week was \$35,485; of the Germania, 12 cars, \$25,717.34; of the Pascoe, \$1675. The Stormont sent up, on the 25th, silver bars valued at \$3224. The Alice reported, on the 29th, 19 bars of bullion, \$16,100.64. Ore receipts were: By Wells, Fargo & Co., \$21,300; by McCormick & Co. (including \$1270 Queen of the Hills), \$18,330; by T. R. Jones & Co., \$18,575.57.

#### List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in Dewey & Co.'s Patent Office Library, 262 Market St., S. F.

FOR WEEK ENDING JUNE 29, 1886.

- 344,563.—BELTING—J. D. Channell, Nevada City, Cal.
- 344,519.—SETTLER—Clayton & Mackie, Salt Lake City, U. T.
- 344,520.—CONCENTRATOR—Clayton & Mackie, Salt Lake City, U. T.
- 344,357.—MECHANICAL MOVEMENT—S. Desvisme, Los Angeles.
- 344,370.—WHISTLE, MATCH SAFE AND CIGAR CUTTER—A. Greth, S. F.
- 344,373.—SIGN—H. L. & W. L. Harris, S. F.
- 344,654.—GAS REGULATOR—H. L. & W. L. Harris, S. F.
- 344,532.—ELECTRIC LIGHT REFLECTOR—W. A. Jones, S. F.
- 344,538.—LAMP FILLER—J. M. McFarland, Virginia City, Nev.
- 344,456.—BRIDLE BLIND AND LOOP—H. J. Noyes, S. F.

- 344,682.—ANIMAL EXTERMINATOR—M. Scholl, S. F.
- 344,689.—CARRIAGE GEAR—Edward Squires, Beaverton, Oregon.
- 344,466.—KNITTED STOCKING—Frank Wilcomb, S. F.
- 16,758.—DESIGN, BRIDLE BIT—W. Davis, S. F.
- 16,762.—DESIGN METAL INGOT—F. B. Morrow, S. F.

#### Mining Share Market.

The holidays closed up mining stock operations for several consecutive days, but some little activity is being shown. An important improvement in the Comstock shaft and middle Comstock mines helped the market. Good ore has been found in the face of the station being cut out for the 3200 level from the Combination shaft of the Chollar-Norcross-Savage Companies. This station occupies the entire west side of the shaft, therefore is 30 feet in width. It has been excavated to a distance of 20 feet west from the shaft, presenting a face 30 feet wide by about 11 or 12 feet in height. At this point a clay seam was found, smooth and standing nearly perpendicular. Considerable quartz had already been met with in opening the station, some of which gave low assays of the precious metals. The apparent clay wall proved to be a narrow seam two or three inches thick. Immediately beyond it a splendid vein of pure quartz was cut into, which showed good ore. Samples taken from various points across the face show it to be a genuine ore vein, and the quartz is of that peculiar sugary, granulated texture and fertile, kindly character peculiar to the bonanza sections heretofore worked in the Comstock, and not partaking at all of the hard and less tractable character found in the 3000 and levels above. Assays from select pieces give results as high as \$100 and \$200 per ton. Superintendent Hamilton shoveled out a sack of it, getting as fair an average as possible, and it assayed from \$2 to \$70 per ton. It may not be classed as a high-grade proposition just yet, but the existence of a strong ore-bearing vein of such a character at that depth and locality is of very important significance. It lies in Chollar ground, 60 feet south of the Norcross south line, near the east side of the great main Comstock ore channel, 300 feet further south than any ore has yet been found in the deep exploration of the middle mines. It is considered to be a continuation of the good ore streaks and deposits heretofore found in the explorations of the Hale and Norcross from the 2400 level down.

#### Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Alice, June 29, \$27,280; Navajo (for June), \$51,236; Silver Bow, 30, \$18,160; Lexington, 30, \$17,920; Dexter, 30, \$3200; Stormont, 28, \$3224; Hanauer, 29, \$5425; Germania, 29, \$3825; Alice, 30, \$16,100; Pascoe, 29, \$1675; Germania, July 1, \$4499; Alice, July 2, \$16,692; Germania, 2, \$4293; Hanauer, 2, \$5895; Pascoe, 2, \$1505; Queen of the Hills, 2, \$1300; Hanauer, 3, \$2900; Germania, 3, \$4433; Germania, 4, \$2161; Hanauer, 4, \$2900; Stormont, 4, \$2230; Queen of the Hills, 4, \$1400. The shipments of ore out from Salt Lake City for the week ending Saturday, July 3d, inclusive, were 36 cars of bullion, \$69,832 pounds; 14 cars of ore, 403,400 pounds; 5 cars copper ore, 143,400 pounds; total, 1,416,632 pounds.

#### Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

#### Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

JAMES' PATENT ORE CAR.

This Car has two double Tread Wheels that carry it on two pieces of scantling laid side by side, two inches apart, making a track ten inches wide for the car driver to walk upon, and only requires a narrow space in the tunnels or drifts for the track. **PRICE, \$35.00.**

We have recently furnished the contractors the machinery for LA TRINIDAD (300 tons per day) and SILVER QUEEN (100 tons per day). These mines are located in Mexico and owned in London. The Process is the Wet Concentration and the plants are, without doubt, the most substantial and complete ever built.

25, 27, 29 &amp; 31 MAIN ST., SAN FRANCISCO.

91 &amp; 93 FRONT ST., PORTLAND, OREGON.

## TATUM &amp; BOWEN,

## JAMES' PATENT ROCKING STAMP QUARTZ MILL.

PRICE, \$350.00.

CAN BE SEEN IN OPERATION AT OUR WORKS.

It is the CHEAPEST, SIMPLEST, MOST DURABLE and EFFECTIVE MILL for the Reduction and Amalgamation of Gold Ores.

NO WEAR EXCEPT ON SHOES AND DIES.

Combined weight of Boss and Shoes (1400 lbs.) is alternately imparted to EACH Shoe with any requisite degree of rapidity.

It saves a higher percentage than any other machine, and requires no skilled labor to set up and run. Weight, 3000 pounds. Capacity, 6 tons in 24 hours through No. 40 Screen. Requires 4 H. P.

## NOTICE TO MINING MEN!

### SILVER PLATED AMALGAMATING PLATES FOR SAVING GOLD!

Get our Prices before ordering elsewhere. Samples furnished on application.

SAN FRANCISCO NOVELTY AND PLATING COMPANY, Removed to 108 First St.

JUSTINIAN CAIRE, Dealer in Mining Material, Agent, 521 &amp; 523 Market St., San Francisco.

NOTICE TO MILL MEN.—All our plates are guaranteed to have the Full Weight of Silver agreed upon, and are all tested before leaving our Works, thereby avoiding the complaints about light-weight, made so often formerly before our starting in this branch of business. PLATES CAN BE FURNISHED AT ANY PRICE REQUIRED.

Centrifugal Roller Quartz Mill.

## IMPORTANT TO GOLD MINERS!

### SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.

BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.  
E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR &amp; CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

## CINCINNATI

### CORRUGATING COMPANY.

## Over 1500 Tons Iron in Stock!

FOUR WIDTHS OF CORRUGATIONS MADE!  
STANDING SEAM PLAIN ROOFING!  
All Paint Re-ground in Pure Linseed Oil!

DEWEY &amp; CO., { No. 252 MARKET ST. } PATENT AGENTS.

JOHN F. HAZEN, Prest.

JAMES HICKS, Treas.

J. G. BATTELLE, Sec'y.

## JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

DUNHAM, CARRIGAN &amp; CO., San Francisco, Cal.

## SQUARE FLAX PACKING.

Finest Packing in the world. Trial Samples sent free. Send for circular. Best of references. Manufactured by W. T. Y. SCHENCK, 256 Market St., San Francisco,

**STURTEVANT MILL.**

This Mill as a Crusher and Pulverizer is without rival.  
Is in operation in leading smelting works and mills.

## JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.  
Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.  
Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

## ADAMANTINE Shoes, Dies and Crusher Plates

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been for the last ten years; we warrant them to out-wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break AT THE SHANK, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.  
For further particulars, address

### CHROME STEEL WORKS,

H. D. MORRIS, Agent, 22 Fremont St., San Francisco.

## THE FRISBEE-LUCOP MILL,

A CENTRIFUGAL ROLLER MILL  
—FOR WET OR DRY—

Reduction of Ores, Quartz, Phosphate Rock, Carbon, or other Mineral Substance to any degree of fineness in a rapid and economical manner.

Any method of amalgamation may be applied.

At 300 revolutions per minute will pulverize 2000 pounds of quartz per hour to 60 mesh dry, and from 3000 to 6000 pounds wet.

All wearing parts easily and cheaply replaced. May be seen in operation at the New York Metallurgical Works, 104 and 106 Washington St., and Pacific Iron Works, San Francisco. Certificates as to performance of the Mills, and any information required, furnished on application.

THE FRISBEE-LUCOP MILL CO.,  
Office, 104 & 106 Washington St., NEW YORK.

OR PACIFIC IRON WORKS, SAN FRANCISCO.

## CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

### Sporting, Cannon, Mining, Blasting and HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

**No. 1 (XX) is the Strongest Explosive Known.**  
**No. 2 is superior to any powder of that grade.**

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

THE CONSUMERS' COMPANY.

## VULCAN B B AND AJAX.

The Best LOW GRADE EXPLOSIVES in the Market.

SUPERIOR TO BLACK OR JUDSON POWDER.

AJAX and VULCAN B B POWDERS are Unequaled for Bank Blasting and Railroad Work.

Caps and Fuse of all Grades at Bottom Rates.

VULCAN POWDER CO.

218 California Street, San Francisco, Cal.

## THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,

Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE, which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

BANDMANN, NIELSEN &amp; CO.,

CAPS and FUSE for Sale.

GENERAL AGENTS. SAN FRANCISCO, CAL.

CALIFORNIA

## ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

OFFICE, 404 MONTGOMERY STREET, SAN FRANCISCO.

EGBERT JUDSON, President.

ALBERT H. REICHLING, Secretary.

## HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

**RANKIN, BRAYTON & CO.,**  
BUILDERS OF  
**MINING MACHINERY.**

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

## WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, A MOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER OF INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

**Baker's Mining Horse Power.**

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

## California Quicksilver Ores.

California is the only State in the Union where quicksilver ores are found and mined. Here the only quicksilver ore of great importance is cinnabar, although metacinnabarite, the black sulphide, is rather abundant in a few mines, and metallic quicksilver sometimes accompanies the deposits of its compounds. The metacinnabarite described by Dr. G. E. Moore was amorphous, but according to Mr. Goodyear it also occurs as minute crystals. Cinnabar is found in a great number of localities in the Coast ranges for 100 or 150 miles north and south of San Francisco, always, so far as known, in metamorphic rocks of cretaceous age. Dr. Geo. F. Becker, in his geological sketch of the Pacific Division, in the census reports, states that the metamorphism is generally peculiar, and the so-called quicksilver rock is readily recognizable. It is a silicified chert-like material often reddened by iron-oxide, and usually accompanied by serpentine or serpentoid matter. In almost all cases pyrite or marcasite and bituminous matter accompany the cinnabar, and mispickel and copper pyrite are reported in a few instances. At Sulphur Banks, on Clear lake, native sulphur occurs in quantities with the quicksilver ore, and native gold has been found on water-worn masses of cinnabar not far from the same locality. The usual gangue minerals are quartz, calcite and magnesite.

Cinnabar does not occur in well-marked veins, but generally in irregular bodies distributed through the rock. In the New Almaden mine, which has been more extensively worked than any other in the State, these bodies appear to lie on a curved surface, indicating a geometrical relation between the position of the several ore bodies, though an obscure one. At this mine the masses of ore are usually connected by tiny seams of the same material. There is a strong similarity between this mode of occurrence and that of many lead-ore deposits in limestone, and it may be, Dr. Becker thinks, that their true character is the same.

The quicksilver country north of San Francisco is a volcanic region, while to the south volcanic rocks are subordinate in some localities and wanting in others. To the south, too, there is no indication of recent deposition of the ore, while to the north deposition is still actually in progress. No general inference to the genesis or age of the deposits can therefore be drawn without fuller investigation (which is now going on under the direction of Dr. Becker, of the U. S. Geological Survey), while the great similarity in the association of minerals suggests a similar origin for most of them.

It is reported that the railroad company has bought a third interest in the recently-discovered coal mine on Clover creek, Shasta county, and if, after running a 70-foot tunnel, it continues to hold out as good as present prospects, they will put in a branch railroad.

## Improvement in Rock Drills.

It is usual in machine or power drills to hold the drill constantly to the base of the hole. Where the rock is seamy the drill has a tendency to go off at an angle and then cramp or bind itself. This is caused by the seam which makes the rock immediately adjacent to or in front of it break off at an angle, and the end of the drill-bit being always against the base of

drill, whereby it is adapted to be thus retracted without interfering with its rotary movement; in a peculiar chuck on which the drill is mounted, and in the general combination of operative parts.

LICK OBSERVATORY.—In regard to the Lick Observatory it is stated that it is expected that the great dome and telescope will be completed some time next summer, and the whole im-

Fig. 1. Section through YZ.

Fig. 2. Section through WX.

Fig. 3. Enlarged Longitudinal Section through Hearth-Plate.

## FURNACE FOR ROASTING BULLION.

the hole, has no opportunity to correct this and straighten the hole, its ordinary rebound not being sufficient for this purpose; but by positively retracting the drill, it is enabled to come back in contact with the high point of the hole just behind, and thus to straighten it. Again, where a down-hole is being made, it is very difficult to reduce the pulverized and broken pieces of rock to a pulp; but by positively withdrawing the drill a short distance between blows it will permit the water which is poured into the hole to get to the bottom, and reduce the debris to a pulp of such consistency that it can readily be discharged.

Chas. O. Barlow of this city has just patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, a device to overcome these difficulties. It consists in a novel means by which the drill-bit is positively retracted from the bottom of the hole, and allowed to spring forward again between the intervals of the blows. It consists further in the peculiar means for mounting the

mense establishment be ready to turn over to the University of California in a little over a year from this date. Of the original \$700,000 devised by James Lick for the construction of the telescope and observatory, it is thought that about \$500,000 will have been expended, and the remaining \$200,000 will be turned over to the University Regents as a partial endowment for its maintenance. This amount will be insufficient for the purpose, as the salaries of a score of competent astronomers and their assistants and the other expenses will amount to at least \$20,000 per year. A considerable deficit will, therefore, have to be provided by the State or by private munificence.

HERR KRUPP has contracted to supply China with 1500 tons of rail at a price, including freight, 25 s. below the lowest English offer.

JOHN W. MACKAY, the mining millionaire, has returned to this city. He will remain on the coast for some little time.

## Furnace for Roasting Bullion.

On page 35 of this number of the PRESS is an article descriptive of the process used for refining copper bullion on the Comstock. The iron Chili mill for crushing said bullion is described in the PRESS of June 19th, on page 405. The roasting furnace, a small reverberatory used only for bullion in this process, is shown on this page. Its construction is shown in Figs. 1 and 2. The hearth (Fig. 3) was composed of two cast-iron plates bolted together and bedded in sand. The furnace walls were recessed on all sides of the plates, as indicated in the drawing. This construction allowed the expansion and contraction of the hearth and prevented the charge from spilling over the edges of the plates. Iron plates were used, in order that no bullion should be left on the hearth after a charge had been drawn, a matter of importance in making tests and in refining for other companies, some of which, as the Bonanza firm, were very particular in their requirements. The space between the hearth and the chimney served as a dust chamber and proved of ample capacity, the amount of "dust" formed being small.

Red bricks were used, except for the parts directly exposed to the flame. The mortar for all inside work was a mixture of sand and clay (materials, by the way, to be had for the hauling), lime being used only for the masonry not affected directly by the fire. The arch was built of one layer of brick set on end and covered with a bed of sand. Air-holes (not shown in the sketch) were originally provided for admitting air through the fire-bridge and the arch to the hearth, and also through the wall into the fire-place, but they seemed to serve no useful purpose, and in time became obliterated. The chimney was 9" x 15" in section and 24 feet high.

The fire-place for the sulphurizing kettle was built against the chimney, into which its draft was led. When the kettle was in operation any escaping sulphur fumes were conducted into the chimney by means of an arrangement of wood and pipes of very light sheet iron which could be raised or lowered at pleasure.

NOGALES.—A dispatch from Nogales, Arizona, dated July 13th, says: The Nogales and Sonora Mining and Smelting Company start their smelter in operation to-morrow morning. They now have about 40 carloads of ore here from their mine, situated near Llano. The Mexico Company have put a number of 12-mule teams hauling ore from their mine to Llano station, and expect the smelter to run without interruption.

DURING the month of June shipments of quicksilver were made from Calistoga to San Francisco by the following mines: Great Western, 137 flasks; Napa Consolidated, 131 flasks; Sulphur Bank, 67 flasks. Total for the month, 335 flasks, or 25,460 pounds. The metal is worth \$36 per flask, and the month's shipments were therefore worth \$12,060.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

## Natural Gas.

EDITORS PRESS:—In a former letter from this point I alluded to natural gas. This phenomenon, for it deserves that name, is growing in importance, and impresses one as the greatest fact in this busy city.

Pipes are being laid in all directions, some of the mains 24-inch diameter, and it will only be a short time when the soot and grime of Pittsburgh will be a thing of the past.

The influence on manufactures will be enormous, especially in the glass interest, where the absence of soot and its contamination is a matter of much more importance than convenience and saving in expense.

Already there are being made here varieties of glass, for mirrors for example, that it has been impossible to produce with bituminous coal for fuel.

The influence on general manufactures throughout the country is another problem.

In so far as iron working and iron making, the effect will not be so great as in some other industries involving high heating.

A steel manufacturer said to me to-day: "How can gas much cheapen my work when I melt four pounds of steel with one pound of slack?" Sixty cents for fuel to melt a ton of steel cannot be much improved, certainly!

I visited the Edgar Thompson Steel Works recently and found the soot and smoke had disappeared.

These enormous works, now producing over 600 tons daily, are being extended, and as the price of rails, the only article made there, is \$10 per ton higher than last year, there is, of course, a large profit.

Reverting again to gas, who would suspect that "smoke" has been the main cause of that backward policy in Pittsburgh which contrasts so unfavorably with Cleveland, its near neighbor, and many other cities that could be named? People sometimes call it an "Old Virginia" town when they pay a cent toll to cross the bridges, stumble over the cobblestone pavements and look up, in vain, for street names to guide them.

It was smoke—the smoke of despair. No one felt like building a fine house in such a place, and no one dreamed of keeping a house or other thing clean. Enforced dirt begets slovenliness and an indifference to surroundings.

Now, all is changing. New buildings of vast size and beauty are being erected, Pittsburgh has reached a *renaissance*, and in my opinion her manufactures will soon extend beyond "iron bars, plows and wheelbarrows." There are, of course, some "exact" manufactures here, creditable ones, but not what the natural advantages suggest.

What if the gas supply fails? is the natural and first question of people who come here. Only this: That Pittsburgh will be the first city to generate and distribute gas; nothing more. That this is to be the future method of supplying cities with light, heat and power, is, in my opinion, a certainty of the future.

Think of sending the product of a coal mine 50 miles distant in the form of gas and contrast that with transporting and distributing the coal! The cost of transporting would be almost eliminated, and when we consider the dirt, expense and inconvenience, the wonder is that coal has so long been hauled to market here. The gas system has come to stay, in some form.

The people here are of the sturdy old Scotch-Irish Presbyterian type, with a liberal admixture of the German or "Pennsylvania Dutch." The physique of the people forms a study, and, in my opinion, is unequalled in America outside of the Pacific Coast. I claim nativity here, and have fulfilled a long-cherished desire to revisit after 40 years the old haunts of boyhood.

Except one man, I found nearly all familiar names in the churchyard. The work of 40 years in this country means elimination.

Pittsburg, June 25th. J. RICHARDS.

## Stamp Mills and Pulverizing Machines.

EDITORS PRESS:—There is considerable discussion at the present time regarding the merits of the rolling, pulverizing and grinding machines as compared with stamp mills. It seems to the writer that there is too much prejudice shown on each side of this question.

The centrifugal, cannon-ball, pulverizing, rocking and rolling machine, in whatever shape it comes, or by what name known, as soon as it meets the eye of the "old pioneer," is greeted with a contemptuous snort, and after looking at its operation for 15 minutes the stiff-necked adherent to the theory that "there is nothing like stamps" turns on his heel and predicts that the machine will wear itself out in three days, and declares to the first man he meets that "these new-fangled humbug grinding machines are ruining the country."

And yet there are many places in this State as well as Nevada where different kinds of these

"new-fangled crushers" are working on ores, and when increased crushing capacity is required, more of the same kind of machines are bought and added to the original plant. This looks as if they gave satisfaction in some parts of the country, anyway.

Mr. Thos. Machell, who is probably one of the best practical amalgamators in the State, and a staunch champion of the stamp mill, paid a visit to an adjoining county to start up a "new-fangled" rolling crusher. After running it three weeks, he states the machine to be fully equal to a stamp battery as a gold-saver and for some kinds of rock superior to stamps as a crusher; the machine runs with less power and costs only one-third as much as a stamp mill of the same capacity. Opinions of this kind are worth considering. Some amalgamators say, "It's all right about your grinding machines crushing quartz—they crush all right, but they don't save the gold; there's nothing like the battery to save gold."

The reason better results are sometimes obtained from stamps than by grinding machines, may be owing to there not being enough amalgamating surface for the amount of rock crushed. It is possible to overcrowd even a stamp battery.

The writer, some years ago, while prospecting in Colorado, visited a stamp mill at the request of the superintendent, and was asked if he could explain why the rock did not pay better. It was then paying only \$4 per ton; the mill had double discharge mortars and all the rock crushed passed over one apron plate only about four feet long; the superintendent was advised to close one discharge and run with one screen only. As soon as this was done the rock jumped to \$7.50 a ton.

Quartz that is porous and in which the gold is loose can be "crowded;" so can most of the slates which carry gold. Sometimes as high as four tons to the stamp can be successfully crushed and amalgamated in each 24 hours, but hard quartz containing fine gold evenly distributed through it must be finely stamped, and requires more time. Perhaps amalgamating pans may yet be found to give the best results after the rock has been run through these revolving grinders.

Many new quartz-crushing machines have been denounced and condemned because they failed to extract gold from quartz that had none in it to start with. This is not fair. Many stamp mills, modern stamp mills at that, have been built on worthless mines, sometimes through ignorance, often for other reasons; but no one expected them to hammer gold out of barren rock. The cost of a stamp mill is a great drawback to the majority of miners, and if anything can be constructed that will crush quartz equal to stamps, and at the same time save the gold, in the name of the great horn-spoon let us know it at once, provided the machine can be had for a moderate price.

If those who are now using these different rolling, crushing, rocking and grinding machines would write their experience with them to the PRESS, it would be a benefit to every miner in the State.

CHAS. L. LANG.  
Sonora, Tuolumne Co., Cal.

## An Arizonian's Opinion of Alaska Mines.

Alex. Levin, of Tucson, has received a letter from Fred Stevens, who went to Alaska in search of some supposed gold placers in that far-off land. On his arrival he was glad to accept a position as batteryman in the largest quartz mill in the world—120 stamps. Writing of this mill he says:

"I have to take care of 12 batteries (60 stamps) and the self-feeders, keep them in order and see that they do their work. My wages are \$90 per month and board, every room being well furnished and provided with hot and cold water for two men to each room. The mill is run by water power; the free gold is saved on copper plates and the tailings are concentrated. To each battery there are two Frue concentrators (altogether 48). The concentrations are worked by the chlorination process. The monthly cleanup is between \$80,000 and \$100,000. The ore is low-grade, but there is so much of it and so handy that it pays first-rate. The mine is worked just like a quarry. It is 650 feet through the ledge. This work is done by Chinamen and natives; strangers find it very difficult to obtain work of any kind."

In conclusion he remarks:

"This is a nasty, wet and cold country; a man's wardrobe is not complete without a pair of rubber boots reaching to the hip, a slicker, and a 'sou'wester'; all the travel being in open canoes, you are liable to be drenched at any time. I am just now on night shift if you can call it so, because, on a clear day, we only light the lamps in the mill from 11 P. M. to 2.30 A. M.; the sun sets at 10.30 P. M., but it never becomes real dark. I sleep in a close room in daytime, under two pair of heavy blankets (can't use Tucson blankets here).

"I wish I were back in Arizona, but I have to get even first on Alaska."

A SPECIAL committee on railroad axles have reported that iron axles are safer than steel axles; that all cranks should have the webs hooped; that as iron cranks appear to fail after running some 200,000 miles, and steel after 170,000, it is highly desirable that they should be taken off and not again used on passenger engines.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ELECTRIC LIGHT REFLECTORS.—Wm. A. Jones, S. F., assignor of one-half to George W. Percy. No. 344,532. Dated June 29, 1886. It is the main object of this invention to correct the unequal distribution of the light peculiar to the electric arc light, and at the same time to increase the projected power of the rays by relieving them from the law of angular projection. This will enable it to illuminate portions of the distant field with greater effect. Secondary objects are, by the proper disposition of intervening reflectors, to catch the rays and divert them, so as to illuminate the shadow of the annular reflectors in the lower field.

LINIMENT.—J. W. Laner, Mountain View, Santa Clara Co. No. 344,051. Dated June 22, 1886. This is a composition which is intended as a corn remedy. In using the composition it is applied with a brush to the corn several times successively, if necessary, and the corn is heated to dryness by some suitable means, as by holding it near the fire, or by forcing hot air upon it by means of a bellows. The corn becomes soft and it is then filed or sand-papered down until it has entirely disappeared. If there is any soreness it is removed by the application of the composition, and the treatment is entirely painless. It may be used for corns on the lower animals as well as on human beings.

TWO-WHEELED VEHICLE.—Milton Newell and Joseph O. Litten, Fresno City. No. 344,129. Dated June 22, 1886. These improvements consist in the peculiar arrangement of springs, a frame carried thereby, and thorough-braces on the frames for carrying the body, and in novel adjustable jacks for supporting the springs and adjusting the body. The object of the invention is to do away with the unpleasant motion occasioned by the "jogging" of the horse, and also to provide for a simple and effective means for adjusting the body.

DEVICE FOR TAPPING CANS.—Charles E. Quigley, Oakland. No. 344,199. Dated June 22, 1886. This device is for conveniently tapping oil or other cans. It consists of a thickened boss of suitable metal or composition, through the center of which a hole is to be bored, and secured upon the side of a can or vessel at a point where the can is to be tapped, so that a screw-threaded faucet may be introduced and screwed in until its inner end reaches the interior of the can so as to open communication therewith, at the same time making a tight joint and holding the faucet rigidly in place.

SETTLER.—Joshua E. Clayton and Simon F. Mackie, Salt Lake City, Utah. No. 344,519. Dated June 29, 1886. This invention relates to that class of machinery used in silver mills and known as settlers; and the invention consists in certain new and useful improvements in the construction of the settler, difficult to describe in detail without the aid of engravings.

CONCENTRATOR.—Joshua E. Clayton and Simon F. Mackie, Salt Lake City, Utah. No. 344,520. Dated June 29, 1886. This machine is an improved device for concentrating ores, slimes, tailings, sulphurets or other substances in which it is desired to separate the heavier from the lighter portions. We shall give a more detailed description of the machine shortly.

DESIGN FOR BRIDLE BIT.—Wm. Davis, S. F. No. 16,758. Dated June 29, 1886. This design for bridle bits consists essentially in a cheek piece with ornamental "conchas," and the bar of the mouthpiece located above the conchas.

DESIGN FOR METAL INGOT.—F. B. Morrow, S. F. No. 16,762. Dated June 29, 1886. This design for metal ingots consists of a series of short cylinders or frustrums of cones, arising from a common base, by which they are united so as to stand in line.

CLOVER CREEK PROSPECTS.—Quite a mining boom is taking place on Clover Creek, near Millville, Shasta county. A few weeks ago a party of six prospectors went up there and went hard to work seeking out a gold and silver quartz lead; they have kept actively at work and now have an incline of 35 feet run in on a good two-foot wide ledge and are highly pleased with the outlook. An assay will soon be made. Also quite recently a fine coal vein was discovered in the same locality and a party of 12 men are now prospecting it. The mine has been bonded to San Francisco parties. The coal proves, so far, to be a good grade of stone coal. If these discoveries prove to be valuable, the latter especially, there will be a good inducement for a branch railroad to be put in from some point on the main line; and such a road, of necessity, would pass through Millville.—*East Side Times*.

THE first bullion produced by the Tomichi Valley smelter, at Gunnison, assayed 318 ounces silver and 60 ounces gold per ton. The smelter is reported to be treating 50 tons per day, and is erecting another stack.

APEXES don't go in the Frying Pan District. The boys over there say that they have a brass band under contract to come over at a minute's notice to escort the first apex man out of camp.—*Denver Republican*.

## School Experts and Practical Miners.

Apropos of the remarks we made in last week's PRESS on the subject of "Mining Engineers," the following, from the *Denver Tribune-Republican*, is of interest: Judging from articles frequently seen during the past few weeks in exchanges from mining camps, the old-time war between experts from school and "practical" men of the hammer and gad is about to be declared anew. This contest, like the wrestle of the ministers with the devil, bids fair to continue forever.

The "practical" man points to thousands of ruins of mills which dot the hillsides and rot on the banks of mountain streams, and other thousands of worthless and abandoned mining claims, as monuments of expert folly. In reply the school man points to ridiculous failures in metallurgical work as the monuments that condemn the "practical" man. It is difficult to tell which has the best of the other in scoring failures. But these failures prove the superiority of neither. They simply prove that the individuals who undertook them were not fitted for their work. There is not a trade or profession known which is not constantly scoring as many or more failures as are made in mining or ore treatment by either school men or practical men. The difference is that mining failures remain as tell-tale monuments, while others leave no mark. The failures of the doctor are buried from sight, and the failures of the lawyer leave no record and are soon forgotten and never understood.

Really the error, so far as the school man is concerned, is as much on the part of the public as on that of the expert. The public persists in considering every boy who comes from school with his brand-new degree of M. E. as an expert. Really he is only a boy who has been taught how to study, what to study and where to look for information. He is no more fit to be called an expert than a boy fresh from a law school is fit to go upon the bench as a Supreme Court judge. If he passes himself off to be anything else but a student he is an egotist who is not likely to ever know much, or else a rascal. On the other hand, the "practical" man, as a rule, has no conception of the vast amount there is to be learned in the science of mining and metallurgy of which the books treat, and the alphabet of which the schools teach. There are some exceptions to the rule. There are practical men of education and culture who have never attended a mining school, but who have systematized ideas and are as well posted on the contents of books and are as skillful in the use of the crucible and beaker as the best of school men. But such men, of course, are rare, just as able men are rare in every profession and calling. The truth is, that the average practical man makes an ass of himself when he attempts to deal with the theoretical and scientific part of the work, about which he knows nothing; but in that which he has learned from experience he is a real expert.

The school man also makes an ass of himself when he sets up his judgment on the many points upon which good judgment is formed only by practical experience and time spent in labor. Both classes have their place in mining work. If either is to be more blamed than the other for blunders, it is the school man, for he should know enough not to blunder; he should know how little is knowable and how little he knows. There is but one real expert in mining matters; he is the man who combines theoretical and practical knowledge; who has got his lesson by studying the accumulated knowledge of all who have gone before him, and handling the pick, gad, hammer and drill in shaft and drift and stope, and who combines with such knowledge that rarest of all gifts—common sense.

"FOG" IN A MINE.—The Bangor (Maine) *Industrial Journal*, in speaking of the Rozier mine, says: Zinc ore has been discovered in the drifts above No. 3 shaft. It is about four feet wide and has the appearance of leading to a large body; it does not follow the tunnel but diverges to the west. It is very near the surface and a few days' work has opened it up; it is now looking finely. Work on No. 1 is suspended on account of foul air. The superintendent and two men went down Sunday and built a fire for the purpose of driving out the bad air. They then started to ascend; when up between 100 and 200 feet, they came into the gas which filled the passage like fog. They forced their way through it and barely reached the surface in a very exhausted state. The shaft is now down about 420 feet and will have to remain till machinery can be put in to purify the air.

A DEGREE AND NOTHING ELSE.—A well-posted mining man said to a Colorado newspaper man that the State is full of mining engineers who have got a degree and not much else. He said that not one in ten of them can tell the different geological periods and the order of their occurrence, or have the faintest idea of "Schmidt's rule," or can name the metals belonging to each of the six groups and their deportment in the presence of different standard reagents. Some of these fellows inflict themselves upon a suffering community as experts and receptacles of scientific knowledge.

## Refining Coppery Bullion Produced by Amalgamating Tailings.\*

NUMBER I.

## The Process Used on the Comstock.

The process to be described, whatever other merits (or demerits) it may have possessed, certainly proved a financial success under the conditions of the locality where it was introduced and where a refining process had been sought previously in vain. I have ventured to bring it to the notice of the institute in the hope that it may prove of some interest as a solution of a practical problem, such as is often presented to the metallurgist in the remote mining regions of the West.

The method was used first at the Lyon mill at Dayton, Nev., and has been adopted at other tailings mills on the Comstock. These mills treat two classes of tailings: "sand," or material which has passed previously through the pans of the ore mills; and "slimes," or the fine clayey material, which, coming from the battery, is too light to settle in the tanks inside of the mills but is caught in large reservoirs outside. The slimes, never having been worked, are naturally richer than the sands; but the assay-values of each class vary considerably among themselves. At the Lyon mill the sand assayed from \$5 to \$7 and the slimes from \$15 to \$25 per ton.

The tailings are amalgamated in combination pans (of wood and iron) with the aid of salt and bluestone. The best results have been obtained when, through the free use of sulphate of copper, the bullion produced has been very base. At Dayton the fineness of the bullion was kept designedly at from 150 to 250.

## The Amalgam.

The amalgam is taken from the canvas strainers and retorted in cylindrical iron retorts, during which process, when properly conducted, the resulting bullion separates into two distinct parts. Next to the retort-body there is a shell of compact and partially fused material, nearly white in color (and hence called locally "white bullion") with more or less of a reddish tinge. On top of this last, in the more central part of the retort, there is a reddish-brown, porous and comparatively brittle mass of what is called (by comparison) "base bullion." The latter is easily crushed and had been roasted and treated with sulphuric acid. But the white bullion had resisted all attempts before made to refine it. It was too dense to allow of crushing, and its composition, about one-half silver and one-half copper, did not permit the successful use of any of the separating processes which had been tried.

The problem presented was to refine the material mentioned by some simple, cheap and quick process which did not require the establishment of any expensive plant or the services of any specially trained workmen, and which would not cause loss of precious metal. For, although the heavy and constantly increasing discount on the value of the silver in this product and the total loss of the copper (which was not paid for) rendered a refining process very desirable, yet on account of the losses incurred in previous trials the general management of the Lyon mill had become very cautious and skeptical in the matter, and disinclined to incur any more expense in experiments. After some demur, at the end of 1873 a trial on one month's mill-run was allowed. No apparatus or material was used except that already on hand. The retort-bullion was assayed in advance and the assay returns handed in. At the end of the experiment (during which no attempt was made to keep the fine silver separate) there was a very careful cleanup and the return in melted bullion bars was compared with the assay reports.

Attached to the mill were sulphuric acid chambers and a bluestone factory. There were on hand a small, decrepit five-stamp battery for crushing wet the base bullion, a small roasting furnace, dissolving tubs, crystallizers and an old refining kettle. I afterward substituted an iron Chili mill for the battery, and added two silver precipitating vats (using old settlers lined with lead), two or three filter-tubs and a precipitating room; and, when the furnace was burned out, rebuilt it in a more convenient situation in a room of its own. This comprised all the new plant ever erected. I give here the result of the first trial as copied from my books. Assays were repeated many times and made very exactly.

The process may be summarized as follows:

The base bullion is crushed and roasted dead in a reverberatory furnace to form oxide of copper and metallic silver (and gold).

The white bullion is treated with sulphur in a closed vessel at a low heat, forming sulphide of silver and of copper. This is crushed and roasted to form oxide of copper and sulphate of silver (Ziervogel process).

## The Roasted Products.

The roasted products are treated (separately as a rule) with hot dilute sulphuric acid (chamber acid). All of the copper (oxide) is thus converted into soluble sulphate. The silver sulphate also goes into solution. Moreover, as

dilute nitrogenous sulphuric acid dissolves metallic silver to a considerable extent, an additional amount of silver sulphate is obtained in solution. Some of the silver apparently remains oxidized after roasting, and dissolves in common sulphuric acid; that is, acid which has been concentrated. The Omega refinery used such acid (diluted), but the amount of silver sulphate obtained from the base bullion was much less than at Dayton, where chamber acid was used. A large part of the silver in the roasted products and all of the gold are left as residues in the dissolving tubs, and (after leaching, drying, etc.) are melted in black-lead crucibles to refined dore bullion.

All the sulphate solutions are removed to tanks containing metallic copper, where metallic silver is precipitated. This product melted gives fine silver bars.

The copper sulphate solutions, after being freed from silver, when of sufficient strength, as was almost always the case, are drawn into crystallizing vats, whence is obtained a fine quality of merchantable bluestone. Weaker solutions are first concentrated and then crystallized. Very weak solutions (wash waters, etc.) are run into vats holding iron to recover the copper, which is melted into bars and used to precipitate silver. The mother liquor from the crystallizers is concentrated and recrystallized, the acid second mother liquor being utilized in the dissolving tubs.

Inasmuch as I have found the correct details of any metallurgical operation, when obtainable, of great value in my practical work, I take the liberty of describing the process in full. If I have fallen into the error of too voluminous description, I have at least avoided the fault of giving favorable estimates in the place of actual working results—a fault not wholly unknown in the annals of the profession. In one place only am I open to the charge of "fudging." In the amount of fine silver produced in 1876 I have included quite a number of ounces which really contained a little gold—sufficient to compel its being noted when stamping the bars. This I have done to avoid injustice to the process and to the workmen employed, who took a pride in turning out good work, and who were sorely troubled at the time at the presence of gold in the "fine silver"—a thing due in the case in question solely to what might be included in the Spanish term *Fuerza Mayor*; to that superior power with which one does not contend willingly. I think my brethren of the profession who have worked under well-meaning and interested, but not always thoroughly-informed high officials, will understand without further explanation.

In all other cases, including the statement of costs, I have given not what might or ought to have been, but what actually was. The expenses of the refinery were increased by the fact that the retorted bullion from the mill was treated of necessity as it was produced, in small and varying amounts. Again, the price of certain materials, as acid, for the year 1876, owing to various causes, was higher than usual. But having chosen this year simply because the full data for this period happen to be handy, while those of other years are temporarily beyond my reach, I feel bound by my limitations to record the exact case.

All data given are those of the Lyon mill, unless otherwise specified.

The terms "white bullion" and "base bullion" are used in their local signification.

Each separate operation was controlled by a system of check tests and weights, which made it practically impossible for any error in working to escape detection.

## Retorting.

The retorts were usually charged with about 1700 pounds each of amalgam. The fires were started about 4 o'clock in the morning, and

[By this is meant sulphuric acid containing one or more of the nitrogen oxides. There is much difference of opinion among those who have written on the theory of chamber acid concerning the precise oxides of nitrogen thus occurring; and it is not intended here to express any opinion on that point. The capacity of such sulphuric acid to dissolve silver is an important matter which has been ignored in almost all the text-books.]

the last fire was given about 8 o'clock in the evening. The temperature was raised gradually from the beginning until the quicksilver distilled freely, and was then kept as steady as possible until the distillation was nearly finished, gently increasing toward the end, when a hot fire was made, and allowed to burn out. Variations in temperature are to be avoided after a proper degree of heat has been obtained; also a too hot fire in the earlier stages of the operation, when the charge seems to melt more easily than it does later.

When the retorts are opened (on the following morning) there are found a dense shell of white bullion and a porous mass of base bullion, as before mentioned. The proportions of these two classes (white and base) vary, partly according to the relative amount of silver in the amalgam, and partly according to the manner of retorting (firing). At first efforts were made to lessen the proportion of white metal, in order to diminish the amounts to be sulphurized. But thereby the proportion of fine silver, and the consequent concentration of the gold in the dore bullion, was diminished correspondingly. After considerable experience it was found peculiarly advantageous to retort thoroughly, and produce as much fine silver as possible without sulphurizing the base metal.

The amalgam was weighed before, and the bullion, both white and base, after, retorting. Averaging all the retorts during 1876 and 1877, we have the following figures:

## 100 POUNDS OF AMALGAM YIELDED

	lbs. white.	lbs. base.	lbs. total.
In 1877, from slime pans.....	4.6	9.0	13.6
In 1877, from sand pans.....	2.77	11.97	14.74
In 1877, from all pans.....	3.24	12.32	14.46
In 1876, from all pans.....	3.0	12.2	15.2
Average from all pans.....	3.1	11.7	14.8

The expenses of retorting were charged to the mill.

## Sampling.

The bullion was afterward removed in one coherent cake from each retort to a low box lined with sheet iron. From each cake three slices, one at the middle and one near each end, about three inches wide, were obtained by cutting the cake completely through with cold chisels in six lines across it. Care must be taken to get with each slice everything, dirt and all, belonging to it. This was secured by laying six bars of iron, in three pairs, under the six cutting-lines; everything falling between the two bars of each pair belonged to the corresponding slices. These slices formed the sample.

The samples were cut up into small pieces, the base and the white being kept separate, and sampled down to six pounds of white and five pounds of base, these amounts respectively forming a charge for the small black lead crucibles in which the samples were melted and from which granulations were taken and treated as in the regular bullion assays. All such assays were made fourfold.

Repeated tests, made at intervals during two years and checked in every possible manner, showed this method of sampling to be satisfactory when done carefully, and when the retorted bullion was substantially free from quicksilver. In order to control all operations of working the tailings, as well as those of the refinery, the bullion was sampled and assayed regularly during my stay at Dayton.

After sampling, the remainder of the retort was broken up into small pieces, and the base and the white carefully separated. All dirt went naturally with the base.

## Assaying.

The fineness of all the bullion from the various mills varied greatly, in accordance with the richness of the material amalgamated and the method of treatment. At the Lyon mill, as before stated, a comparatively steady grade of fineness was sought. The gold followed the copper in its separation in the retort to a great extent, but small fluctuations had no effect. I extract the following from my assay book for the two years already mentioned:

## WHITE BULLION.

Highest silver assay... 652 fine (gold here 0.2 fine).  
Lowest silver assay... 482 fine (gold here 0.4 fine).  
Highest gold assay... 1.3 fine (silver here 571 fine).  
Lowest gold assay... trace (silver here 606 and 616 fine).  
Average assay, 565 silver, 0.4 gold.

## BASE BULLION.

Highest silver assay... 89 fine (gold here 1.9 fine).  
Lowest silver assay... 17 fine (gold here 1.5 & 0.7 fine).  
Highest gold... 3.2 fine (silver here 74 fine).  
Lowest gold... 0.4 fine (silver here 49 fine).  
Average assay, 37 silver, 1.16 gold.

## TOTAL BULLION.

Average assay, 148 silver, 1.0 gold.

I found it quite impossible to get satisfactory results from testing the retorted bullion for quicksilver with the means at my disposal. At times there was a very considerable quantity of this metal, especially in bullion received from other mills, rising apparently up to three or four per cent, and perhaps higher. But on this point I am unable to speak with satisfaction to myself.

## Preliminary Calcining.

For preliminary calcining the bullion in lumps from the retorts was thrown into the hot roasting furnace after a regular day's work therein, and left until the next morning. This was done for two reasons—primarily to facilitate the subsequent crushing, and subordinately to drive off any contained quicksilver, a thing generally unnecessary with our own material, but requisite usually when treating other bullion, in order to protect the roaster. As this entailed no special expense, it grew to be the regular practice with all bullion. The hearth could be filled up to the top of the arch.

The base bullion thus treated was oxidized to a very considerable extent. The average gain in weight for each year, 1876 and 1877, happened to be exactly the same, viz., 17.4 per cent.

The white bullion underwent less change. The average gain in weight for 1876 was 2.8 per cent; for 1877, 2.3 per cent. But there was a certain amount of mechanical effect produced, whereby a greater or less proportion was rendered brittle, so that it could be crushed.

(To be continued.)

## Yield of Comstock Mines.

Only six mines in Storey county returned bullion for taxation for the quarter ending March 31, 1886. The ore output, assay value of the same, and the gross value of the bullion returned are annexed:

	Tons.	Average.	Bullion.
Belcher.....	10,409	\$11 34	\$118,104
Con. Cal. and Virginia.....	30,003	11 60	340,370
Crown Point.....	11,268	12 62	142,275
Kentuck.....	2,989	13 20	39,458
Overman.....	1,740	10 31	17,955
Yellow Jacket.....	11,789	12 66	149,303
Totals.....	62,288	\$12 00	\$816,465

The Consolidated California and Virginia is the only one of the north end Comstock mines that produces any bullion for taxation in the above quarter. The Belcher, Kentuck, Crown Point and Yellow Jacket mines are at Gold Hill, at the other end of the great Lode, and the Overman is a good distance south of the Belcher. It is well to bear in mind that there was no bullion produced in the first quarter this year by any of the mines north of Yellow Jacket, except the one already named. In this boundary are the Utah, Sierra Nevada, Union Consolidated, Mexican, Ophir, Best and Belcher, Gould and Curry, Hale and Norcross, Savage, Chollar, Potosi, Bullion, Exchequer, Julia, Alpha and Imperial. The product of the Belcher and Yellow Jacket mines cost \$6000 and \$22,000 more respectively than the value of the bullion. Crown Point made a profit of \$6000, and Consolidated Virginia had a margin of just \$912. Kentuck lost \$7000, and Overman about \$1000.

The yield for the quarter is 8000 tons greater than for the previous quarter ending December 31, 1885, and the amount of bullion is about \$100,000 larger. For the first quarter of 1885, silver mines on the Comstock produced 57,031 tons ore, averaging \$13.77 per ton, or \$785,594. The mines contributing last year were the same as this year, with the exception of Lady Bryon and Monte Cristo in place of the Overman. A year ago the ore from the Consolidated California and Virginia mine assayed \$15.53, against \$11.60 this year. For February and March, 1885, the mine was partly worked under a lease to Senator Jones. The cost of reducing ores is less than it was in the first quarter of 1885, but it is found impossible, as a rule, to make expenses on \$10 to \$12 per ton ore that carries as much silver as that from the Comstock mines does at present. The Belcher and Crown Point mines were shut down a short time, for needed repairs to machinery. So long as these mines can collect enough assessments, together with the value of the bullion produced, to meet expenses, they will be kept open in the hope that something may be found that will pay better. The bullion product for the quarter ending June 30th is expected to show an increase over that of the first quarter. The gross yield has been estimated at \$1,000,000.—*Bulletin.*

THE probabilities are that two more furnaces will be added to those in blast at the Leadville smelters within the next fortnight, and that before the close of July 20 furnaces will be in operation.

IRON car wheels average about 40,000 miles, while the life of the steel-tired is 200,000.

## Passing Events.

Silver has gone down to a very low price indeed, and no wonder that silver miners on this coast are becoming discouraged. The discount on bullion is a very heavy drain on mining operations and makes the difference between profit and loss in many cases.

In addition to the strike at the Union Iron Works, another one has occurred in this city at the Risdon Iron Works, thus inconveniencing the two largest iron works on the coast. There is no quarrel about wages, but this last strike is an outgrowth of the Spreckels boycott, and is more fully referred to in another column.

There is little to report of note concerning mining matters. Active prospecting is going on in the mountains in all directions. In this State the miners are developing their quartz and drift mines with great vigor, confident in the fact that gold mining pays better than any other kind in these days.

The finding of a \$7000 nugget in a Sierra county drift mine shows the possibilities of mines of this character, and that the era of good nuggets has by no means passed away in California.

The Anaconda Mining Company, of Montana, gives employment directly and indirectly to about 2000 men, and the pay-roll is about \$200,000 per month.

## "Promoting" Mines.

Foreigners who purchase mines in this country generally pay a great deal more for them than they are worth; and, failing to pay good interest on the investment, the mines themselves are held to blame. With very few exceptions, the American mines "floated" on the English market have been put there at exorbitant figures, though the people at this end get only a small proportion of the money. A mine bought here for \$50,000 is placed on the market there for \$250,000 or \$300,000, or even a greater advance. The difference in original cost and selling price goes into the pockets of the "promoters." A delusive prospectus is issued, calculated to inveigle people of small means to buy in hopes of getting large returns from small investments.

A case of this kind has just come to notice where certain Colorado mines in Gilpin county are being put on the London market. The company is known as the Sapphire, and was organized to purchase the Frontenac and Searle mines, in Elkhorn gulch. The capital is £130,000 and £20,000 debentures. The prospectus states that £125,000 in cash and debentures is to be paid for the mines. The Colorado papers are showing up the scheme in rather an unpleasant light for the promoters, for they do not think the mines worth any such price.

The Denver *Tribune-Republican*, in speaking of the prospectus says: "The fact of the matter is that the prospectus was written by an ignoramus, or with the intent to deceive. In either event it is an injury to Colorado, and should be condemned by Colorado miners. Great Britain is in the right spirit to purchase a great many American mines just now, but the spirit will not last long if the investing public is to be treated with allopathic doses of nonsensical falsehoods, or catches a few small mines at prices enormously greater than their actual value. It is plain to be seen that financial circles are everywhere getting something of a mining fever. It is too much to expect that there will be any failure on the part of ignorant pretense and swindling dishonesty to grasp the opportunity; but it is not too much to expect that honesty will sit down as solidly as possible on them at every opportunity."

The Idaho Springs *News* speaks of the mines in question as follows: "The two mines are excellent pieces of properties, and have been producing considerable ore under the leasing system, which has paid well. But they are certainly not worth the outrageous price asked. Years ago they belonged to an English company and were worked under Mr. W. W. Ramage's management, but those times being high-priced times, the properties did not yield satisfactory returns; judgments and other causes finally wound them up. The Frontenac is what was once the old Clifton mine. We hope our English friends will look well into their investments in this country, or else we fear it will turn out to be the 'same old story.'"

Occasionally the English investors are warned in this manner, but as a general thing the mischief is done abroad before the people who buy are well informed by disinterested parties. It is a bad thing for American mining interests to have such schemes organized. There are good mines to be had for moderate prices, but there seems no way to get rid of the objectionable middle-men under the present system of mine bonding and buying.

**HOME MANUFACTURES.**—At a meeting of the California Manufacturers' Association, on Monday, a committee report was received stating that a form had been prepared to be signed by the members of the association and business men of this city and State, requesting all customers to abstain from purchasing goods of foreign manufacture when the same class of goods of home manufacture can be purchased as cheaply. The association has protested against the short notice given in advertising for Government supplies for the coast in the East. In order to make the office of the association a bureau of information, a special form of authorization has been adopted requesting Government officials to assist the authorized representative in procuring necessary information.

The receipts from the North Star mine, of Grass Valley, for the fiscal year ending April 30th were \$129,996, and the disbursements \$115,220.

## Mining Terms.

## "Chutes and Shoots."

The proper use of common mining terms cannot be too strongly recommended, particularly among the English-speaking mining communities of the world. It is not only convenient, but absolutely necessary, to prevent confusion and mistake, that the terms used in describing, reporting on, and even in the keeping of mining accounts should consist of those in common use by practical miners and which do not admit of a double meaning. In conversation on this subject with Mr. Melville Attwood, the well-known mining engineer, he expressed himself as follows on the question of the terms referring to chutes and shoots in mines:

Subterranean mining requires two very distinct classes of workings, the preparatory and those for extraction. The preparatory consists in shafts, levels, crosscuts, and drifts on the course of the vein, from the latter at intervals of say 50 feet more or less, according to the width of the vein—rises, or *chutes*, are made on the vein to the height required to be stoped, so that the vein matter when broken and thrown into the chute may slide down to the drift. The wooden portion of the chute is in the form of a spout, projecting for a short distance into the drift, to which is fixed a sliding door that, on being raised, allows the vein matter to drop into the cars.

Some experts and mining lawyers have taken upon themselves to write "pay chute" instead of shoot. The following authorities, it is thought, are sufficient to settle the question: The Cabinet Cyclopædia, 1839, Treatise on Geology, by John Phillips, F. R. S., Professor of Geology in King's College, London, Vol. II, page 133:

"Another peculiar appearance in mineral veins noticed by William Fox, Henwood and others, and which, from personal inspection, the author knows to be frequent both in primary and secondary mining tracts, is the segregation of the metallic contents of a vein into portions inclined at various angles in different veins, but nearly parallel in the same vein. These are called 'pipes,' or 'shoots,' and their occurrence is of such importance as to mark, in a long vein, a series of parallel spaces more than usually metalliferous. The relation of these pipes of ore to the natural structures of the neighboring rocks is a subject of research strongly to be recommended to intelligent mine agents, both for its practical and scientific value. Mr. Fox observes, from the information of Mr. K. Tregaskis, that when veins are nearly at right angles to the beds of killas, the masses of ore which they contain are generally conformable, in their underlie, to the direction or dip of such beds; in other words, they usually take an oblique direction in the veins, and form what the miners call 'shoots' of ore; and when the directions of the beds and veins are nearly parallel to each other, the ore has not usually any independent dip or shoot in a lode; it is then termed a 'pipe' of ore."

"Glossary of Mining Terms," by R. W. Raymond: Chute (sometimes written shoot)—1. A channel or shaft underground, or an inclined trough above ground, through which ore falls or is "shot" by gravity from a higher to a lower level. 2. A body of ore, usually of elongated form, extending downward within a vein (ore shoot). The two forms of orthography of this word are of French and English origin, respectively. Both are appropriate to the technical significations of the word.

An ore-shoot, for instance, may be considered as a branch of the general mass of the ore in a deposit, or as a pitch or fall of ore.

(Germ. erzfall.) In England the orthography shoot is, I believe, exclusively employed, and this is perhaps the best, the other being unnecessarily foreign.

"Webster's American Dictionary of the English Language," 1875:

Chute (shoot), n. [Fr., chute; O. Fr., chente, from cheer, choir, chair, to fall, from Lat. cadere, to fall; It., caduta; Pr., cazuta, chaeguda.]

1. A rapid descent in a river.
2. An opening in a river dam for the descent of logs, etc.
3. A framework or tube through which articles are made to slide from a higher to a lower level.

Shoot, n. 6. (Min.) A vein running in the same direction as the strata in which it occurs.

## Gold Mining in Japan.

According to Japanese historians, gold was first found in Japan in the year 749 A. D., about 80 years after the discovery of silver. During the 90 years in which the Portuguese exported gold from Japan in such large quantities, this export averaged \$3,300,000 per year, and during one single year amounted to as much as \$12,000,000. The annual export of the Dutch between 1649 and 1671 averaged nearly \$3,000,000.

Most of this great yield was obtained from placer workings, which, being shallow and of small extent, were quickly exhausted, and the attention of the miners was then turned to the quartz veins, which yielded smaller but more constant returns. At the present time mines producing gold alone are not, as a rule, worth working. The average of the best placer beds is not over five and a half cents per cubic yard.

The quartz veins are generally very poor, rich quartz being found only in small, thin deposits. The average value of the quartz is one-half to one-third of an ounce per ton, although, in exceptional cases, the yield has been as high as \$90 to \$100; but where the quartz is as rich as this the veins are so extremely thin as to render extraction exceedingly expensive.

The methods of extraction are very interesting. The gold-bearing quartz is first crushed and then ground with water, repeatedly and in small quantities, between heavy millstones moved by hand until reduced to an impalpable slime. This slime, as it issues from the mill, is largely diluted with water and conducted over a series of short and narrow boards covered with numerous diagonal saw-cuts. These boards, which collect the gold and other heavy metals very perfectly, are frequently cleaned in a tank, and the concentrated material so collected is washed with great care and skill on the board of the gold-washers.

The first working of the ore by this process extracts 65 per cent of the assay value, and by repeated treatment the proportion of gold saved is brought up to fully 90 per cent.

In working gravel deposits, ditches are cut in such a way that the water flows over the bed-rock through the gravel deposit, a certain amount of gravel being brought into the ditch by undermining the bank.

The larger stones are carefully washed by hand and thrown out of the ditch, the smaller ones being separated by the aid of proper tools. The rapid current washes out the clay and fine sand, leaving a bed of fine gravel in the ditch.

When this bed has reached a thickness of about a foot, two or three small straw mats are placed side by side in the bottom of the ditch, and the gravel, little by little, hoed over them. As the gravel is swept over the surface of the mats by the force of the current, the heavy gold and the iron-sand sink between the strands of straw and are retained.

From time to time the mats are moved a few feet down the stream, and the new material so exposed is hoed over their surface, until finally all the gravel has been several times subjected to treatment.

As the mats become charged with gold they are taken from the stream and others substituted. The concentrated material collected by the mats is finally washed with great care on the washing-board, for the purpose of separating the gold.

The Richmond Con. Mining Company, Eureka, Nev., made a net profit for the last half year of \$200,000, of which stockholders were paid \$67,500 in dividends. The product for the year was 13,163 ounces of gold, 444,308 ounces of silver and 2045 tons lead. The lead sold for more money per ton than in the previous year. The receipts from the product sold were \$1,106,000. The value of the bullion unsold, in transit and at the works, at the close of the fiscal year, was \$767,000. This makes a total of \$1,873,000 for the year. But from this sum must be deducted \$770,000 for bullion carried over from the previous year. The expenses for the year were \$357,000, leaving the net value of the bullion produced at \$746,000.

MINING assessments delinquent in July aggregate \$433,400. Of this, \$285,000 is due from Nevada mines, \$114,500 from California, \$30,000 from Arizona, and \$3000 from New Mexico.

The Elk Horn Mining Company, of Montana, has paid 24 dividends in the past two years.

## Common-sense Geology—No. 2.

[Written for the Press by JUSTIN CHENOWETH.]

About three-quarters of a mile southerly from the shaft of which I have spoken, a seam of coal was found outcropping on a flat surface and dipping toward the bay or harbor at Nanaimo. An opening was made and the mine first operated by means of the slope shown in Fig. 4. Subsequently an opening was made a mile distant from the first one, on the same seam of coal, and a working slope carried down parallel to that shown in Fig. 4, as it appears in Fig. 5. In so far as these two figures exhibit the position of the coal, they are exact copies of the working plans in the Vancouver Coal Co.'s office at Nanaimo. Being placed side by side, and in the same scale, they show at a glance the different shapes in which the same continuous seam of coal may lie at points separated by the distance of only one mile. In both figures the heavy lines marked *A* represent the coal. The lines marked *B* the datum lines on the same level as the top of the slopes, that of Fig. 5 being 100 feet above high water in Nanaimo harbor. The irregular lines, *C*, represent the contour of the surface.

In Fig. 4, near the upper end of the slope, there is shown the appearance of a fault. The superintendent in charge of those mines at the time of my visit could not give me any definite information concerning it. I have examined the ground carefully. Neither on the surface nor within the slope is there any appearance of fracture or dislocation of the inclosing rock. I therefore conclude that the fault (if it really be one) is the result of irregular deposition rather than disruption. Elsewhere the coal was continuous and unbroken, as shown in the figures. The inclosing material, as it appears on the surface, or is revealed in the works, is chiefly hard gray sandstone intercalated with strata of hard conglomerate and shale, all solid, without appearance of fracture wherever penetrated.

There is no conceivable combination of circumstances by which a mass of solid rock 500 feet in thickness (the depth to which the coal has been extracted) could be bent from a regular horizontal position to the shapes in which the seam of coal existed as shown in Figures 4 and 5, leaving the coal intact, and the containing rock in the condition of sandstone. Had the rock by means of heat become sufficiently plastic to be bent into such shapes without fracture, it would have certainly assumed a crystalline form on cooling, and the contained coal entirely consumed. But if the system of geology as now taught be true, this Nanaimo seam of coal, originally deposited on a horizontal surface, must have been transformed into the position shown in Figures 4 and 5, by the flexure of the crust of the earth when having a thickness of 20 or 30 miles. The absurdity of a system that requires for its maintenance the presumption of an occurrence so palpably impossible must be clearly apparent to any intelligent mind whenever directed to the consideration of it, if not hopelessly sunk in the ruts of prejudice and preconception.

Geologists teach that the aggregate thickness of aqueous rocks taken collectively is about 10 miles. On the eastern border of Puget Sound in Washington Territory, near the northern extremity, there is a continuous bluff, wave-worn shore of sandstone about 15 miles long, being unmistakably a homogeneous formation without a single stratum of any other kind of rock intervening. There are partings at intervals which, according to geological teachings, would indicate lines of stratification dipping to the northward at an angle of about 45°. This rock unquestionably belongs to what in geological parlance is termed the carboniferous series, as on its northern extremity is situated the Bellingham bay coal mine. Estimated by geological rules this single formation would have a thickness of about 11 miles, equaling that of all aqueous formations collectively estimated under the system.

THERE are some three and a half million pounds of foreign lead in bond in New York.

## Foundry Notes.

Work continues very dull at the city foundries. For some months past large orders have been scarce. There is not as much mining machinery being built this year as usual, and all of our foundries run this class of trade.

The labor troubles in this branch of business continue. This week the Risdon Iron Works have had trouble. The boiler-makers, to the number of 110, left the shops in a body, an occurrence due to the boycott ordered by the Federated Trades against the Spreckels steamship lines. Some time previous to this the Risdon Iron Works contracted with the Spreckels to manufacture several new boilers for their vessels. These orders were reached in their routine a few days ago, but when the men learned who the boilers were intended for they stopped work and marched out in a body from the shop. Although the contract was made long before the boycott against the Spreckels went into effect, the men refused to do the work, and if non-union men are employed a general strike will occur in all departments of the foundry. The strikers themselves say they are perfectly willing to go to work on any and all orders save those for the Spreckels, as in other respects they are fully satisfied with their positions and wages. Robert Moore, the superintendent, in speaking on the subject

boiler-makers walked out and we are not doing it."

John G. Ills, of the Jackson Stove Foundry, has made application to the Molders' Union for men, but that body has requested him to discharge his non-union men first, saying none of the members of the Molders' Union will work until this is done. Ills has heretofore had trouble with the union, owing to the employment of non-union men, and some months ago a strike occurred in his foundry.

At a meeting of the council of the Federated Trades a committee was appointed to visit the various labor unions and state the position in which the federation is placed in regard to the strike of the iron-workers at the Union Works, and with the boycott on the Spreckels steamers, and solicit assistance. The action of the Risdon Works strikes was also sustained, it being held that they had acted in accordance with the union principle.

## A Miners' Organization Proposed.

To the Miners of California:—It has long been apparent to the writer that the mining interest and population of California must awake to their rights and bestir themselves, or the whole area of mineral lands will be absorbed by the rancher and the "Immigration Society," working in the interest of every foreigner and immigrant who lands in our State, and desires

COAL VEINS IN BRITISH COLUMBIA.

says: "We have got work to do for the Spreckels firm on contracts which we entered into three months ago, before there was any trouble between them and the Federated Trades unions, and it must be done. The material for the work arrived only a few days ago, and when I told the men to go to work on it they walked out. They said that they were sorry they had to go, but the Federated Trades unions would not allow them to do any work for vessels belonging to the Spreckels. The trouble was caused entirely by the differences existing between the trades unions and Spreckels Bros. I attended a meeting of the trades unions about two weeks ago, and told them we had contracted to do the work for the Spreckels and would be obliged to do it. As I explained when I appeared before them, they are not injuring the firm of Spreckels Bros. by their strike, but are hurting us, because if we cannot do the work it will be given to some one who can. The work will certainly be done, and the Spreckels steamers will always leave on time, despite all strikes."

Captain Taylor, President of the Risdon, says: "We are working all departments with the exception of the boiler shops and it is not our fault that we are not working them. There is no issue between our firm and the men heretofore employed here. We have always been on the most friendly terms and we have not had occasion to discharge any person in our employ. Certain work came to us and as business men we were obliged to accept it. When the time came for the performance of the work our

Government lands. In every mining county of this State this evil is apparent. Mineral lands, even where quartz lodes plow through them glaringly, and gravel beds which show the mineral, are daily taken up under a solemn oath as not mineral-bearing, until rank perjury seems to be no crime. The Land Office of every district of mining counties shows so much of this perjury that, were just punishment meted out to the perjurers, the State would have to build a new penitentiary to hold the guilty ones. Such is the fact, clear to every miner in every mining county of the State.

Now, the purpose of this article is to say that this business must be stopped; that every one interested in mining must take a hand, assert his rights to the mineral domain, overturn the fraud practiced, and bring to justice every perjurer who has shown himself to be such. To this end there must be organization, and I suggest that every mining county of the State organize a society, allowing as members every operating miner.

Mining districts had better organize separately, appointing, say three of its members as members of a county committee. The county committee to then appoint three of its members to form a State executive committee. As soon as two counties organize, let them appoint a committee to formulate the State organization.

The importance of this move needs no further argument. The requisite is action. In organization is power.

In connection with this land interest comes also the water question, the first contest being the overthrow of the riparian decision of the Supreme Court.

Every vital interest of this State is organized for its protection, except that of mining, and this is the all-important time. What district will be the first to act?

THE OLD MAN OF THE MOUNTAINS,  
Nevada, Cal., July, 1886.

## The Hill "Triumph" Roller Quartz Mill.

There is a very general interest displayed at present among miners and millmen as to the comparative merits of stamps and the various roller mills for crushing quartz, and anything that bears on the results of actual trials is of value to all concerned. One of the Hill Triumph quartz mills has recently been placed in operation in the Bully Chooch mining district, at Cleveland, in Shasta county, by the Joshua Hendy Machine Works of Nos. 39 and 51 Fremont street, this city, for the purpose of demonstrating the practical effective operation, durability and capacity of this style of mill. Learning of this, a representative of the Press asked to be informed of the results obtained, and whether this practical trial had developed the expected conditions. We will let the superintendent of the mill speak for himself, by publishing the following extracts from letters received from him:

Under date of June 25th he writes as follows: "I started the mill on the 23d inst. All of the machinery works well and the (Hill) mill could not possibly do any better work or give any better satisfaction. It is now crushing 10 tons per day and has required no attention except the ordinary work of oiling."

Under date of June 29th we quote: "The mill is running very nicely, and I have had no delay since my last to you of the 25th."

Under date of July 2d he writes as follows: "The mill was shut down last night and cleaned up to-day. In the last 101 hours, or a little more than four days, we have crushed 75 tons of ore, or say 17 tons per day. Every one who has seen the mill running is pleased with it. In the cleanup made to-day I found, somewhat to my surprise, about 75 per cent of the amalgam within the mill, which speaks well of its capabilities for saving amalgam. One roll has been split, but was replaced with only slight delay."

We are further informed by the "Joshua Hendy Machine Works" that another of these mills is in successful practical operation on the property of the Zebra Mining and Milling Company, at or near Bates Station, in Fresno county, California, and we append the following extract from a testimonial letter, dated May 25, 1886, from a former superintendent of that company, in which he writes:

"Having had supervision of the operation of the 'Hill' roller mill, I have this to say in relation to it: That the ores delivered to the mill were of a hard, flinty character, but I found it capable of crushing 15 tons per day of 24 hours. The mill was charged with 45 pounds of quicksilver, and there was no observable flowing of quicksilver or amalgam through the screens; and in cleaning up I was surprised to find that over four-fifths of the amalgam was taken from the mill and the remainder from the outer plates. The operation of the mill was complete, and the power required to drive same was about 8-horse power. The consumption of fuel was one and one-half cords of inferior wood per day."

In a letter dated July 11th, from the present superintendent of the same property, we find as follows, viz.: "I save about 95 per cent of the amalgam in the mill."

The above works have had recently placed on the property of the Central Mining Company, controlled by A. Eastman, S. B. Fowler, and others, situated near Grass Valley, Nevada county, this State, a complete plant comprising ore crusher, automatic feeder, "Hill" roller mill, "Triumph" concentrators, etc., and it will probably be ready for operation on or before the 22d of this month. As the mining districts in the vicinity of Grass Valley and Nevada City have long been celebrated for their large bullion yield and the acknowledged center of the quartz mining industry of our State, we look forward with interest to the reports of the operation of the "Hill" roller mill upon the ores from the mines of that section.

Those who believe only in the superiority of stamp mills for the reduction of ores should consider these facts and give the new machine credit for its work. For the extraordinary percentage of amalgam which these mills are alleged to save within themselves, and the consequent assurance of but a small loss in escaping waste, bring this form of mill in strong contrast with the usual results obtained in the general operation of stamp mills.

If the above stated facts are fully substantiated by the performance of the mill at Grass Valley we shall be pleased, and we believe it will be of interest to our readers, to present at a future date a concise report of the actual practical workings, covering capacity, durability and economy of power, and cost.

## MECHANICAL PROGRESS.

**HAND HOLES IN BOILERS.**—Some manufacturers of boilers, says the *Locomotive*, object to putting a hand hole in the back head of the ordinary tubular boiler, giving as a reason therefor that the hand-hole plate is exactly the same thing in such a location as a soft patch, and is equally liable to give trouble. We do not share in this opinion. A hand-hole should always be put into the back head of a boiler unless there is a man-hole in the front head below the tubes. In this case the hand hole will not be absolutely necessary, but it will do no harm. The idea that it will give trouble is a wrong one. Properly cared for and packed so that no leakage can occur, there never will be the slightest trouble with a hand-hole in this location. Four inches by six inches is the best size for a hand-hole; this allows very effective cleaning to be done through it. Very small sizes are difficult to clean out through, and should always be avoided in tubular boilers of the larger and better kind. In small vertical boilers 3x5 inches is a very good size to put in at the bottom of the water leg and at the level of the crown sheet. But each boiler should have three hand-holes at bottom of water leg and three at the level of the crown sheet. The distance to be reached for scale in these cases is so short that small hand-holes answer very well to work through.

**COMBINATIONS OF METAL AND GLASS.**—At last year's Gorlitz Exhibition specimens were exhibited of a new ware, partly of metallic luster and partly yellow and red, like amber, topaz, or ruby-colored glass. In this new patent process (described in the *Eisen Zeitung*) network of soldered bronze wire, exactly fitting the vessels to be prepared, are pressed into the wooden or iron casting molds, and the mass of glass is then blown in, so that it not only fills up the meshes of the wire netting but partially surrounds the metallic substance, a durable union of the two component parts being thus effected. The articles are decorated with an elegant and tastefully arranged filigree work. In some places the wire netting is brought into contact with small plates of the same metal. The difficulty of the process is the discovery of a suitable metallic mixture, the properties of which are commensurate with the great heat to which the glass has to be exposed. After the casting the metal is completely black, and has to be gilded to restore its luster.

**REST IN IRON.**—A curious bit of experience has been had recently at one of the leading steel mills in the country. A lot of material for a bridge was rejected by the inspector for the buyers, much to the surprise of the producers. After the inspector had left the manufacturers decided to make an independent investigation, which resulted in showing that the rejected material did not come up to specifications. Further research followed and developed the fact that for a given number of hours after the material had left the rolls its physical qualities gradually changed, reaching a period of rest only after a certain time had elapsed. So far as we know, no such observations have yet been made anywhere, and if the facts are borne out by the experience of others, a good deal that is "mysterious" in steel may be explained.

**GENERATING STEAM BY SLAG.**—In most furnaces for separating the metals for their ores a vast amount of heat is lost in disposing of the slag. Mr. Brotherton, superintendent of the American smelter, at Leadville, Col., has patented a plan for generating steam for motive power at the smelters through the use of slag. By this method the slag is dumped into large shallow vessels, which are afterward run under boilers, and the heat used in generating steam. An experimental test of the method resulted in maintaining 75 pounds pressure on a vertical boiler for seven days. If the plan proves practical, it will result in a saving to the smelter of \$1200 to \$1500 a month.

**NO DEAD CENTER.**—A German engineer is reported to be the inventor of an improved construction of steam engine, the peculiar feature of which consists in the dead center point being obviated. In this arrangement a block is secured to the piston rod, this block being provided with a diagonal slot, through which the crank pin passes. The slot has concave edges facing each other, and is provided with a recess at each end. The slide valve is attached to a rod provided at the lower ends with tappets, against which the ends of the sliding block strike, thus reciprocating the slide valve rod. The levers from which the rods are suspended are provided with spring arms for giving the desired degree of expansion.

**HOT BOXES ON PLANING MACHINES.**—In answer to a query in regard to some means for preventing hot boxes on a large, double-cylinder planing machine, a cotemporary says: A tendency to heat in the journals of this class of machinery arises from several causes, but the most common are unbalanced bits, rough or eccentric shaped journals and tight belts. Have a first-class machinist make a thorough examination instead of wasting money in different kinds of lubricating oil. The cause will, undoubtedly, be found in some fault in the construction of the machine.

**AMERICAN HARDWARE ABROAD.**—London *Iron* remarks as follows on this subject: Our American contemporaries have every cause to be surprised at the astonishing fact that thousands of tons of scrap iron are every year taken to the United States and there converted into the simplest of American manufactures, the sad or laundry iron, and then exported back to Europe at no small profit. There is not a corner of Europe where American small cast hardware is not on sale. The toolmakers and machinists of Europe—such as Krupp, of Germany, Whitworth and Armstrong, of England, and Hotchkiss, of France, with their vast resources—are unable to produce a Monkey or screw bar wrench equal to the American wrenches, and consequently they have to import these tools from the States. It is stated that there are no less than 80,000 dozen of them exported to Europe alone every year. It is interesting to note that Charles Moncky, the inventor of this screw-bar wrench, received only \$2000 for his patent, and is now living at Williamsburg, Brooklyn, in a small cottage bought from the proceeds of this sale. In the matter of the common pocket boxwood rules, also, the American manufacturers so far excel all others that, if not all European nations, certainly all nations outside of Europe, are supplied from America. The manufacturers there print on the rule whatever system of measurement is followed by the country for which the goods are intended. American augers and auger bits are used the world over, no other nation being able to compete.

**MACHINE FOR SAWING RAILS.**—A correspondent of the *Scientific American* describes a saw for sawing rails which is in use at Grand Island. It is run by an 80-horse power engine at the rate of 3000 revolutions per minute. The saw is 40 inches in diameter, five-sixteenths inch thick, made of Bessemer steel, with a smooth edge. Two one-half inch pipes keep a constant current of water on it, notwithstanding which the rail for one-eighth inch in front of the edge is made red hot by friction. The saw was made for iron rails, which it cuts in from 20 to 45 seconds. It has been tried on steel rails, though it did not work. It is believed by the present general foreman, B. C. Howard, that the reason is that the feed is too fast, and he intends to demonstrate by a series of experiments whether or not steel rails can be cut by it.

**EXPERIMENTS WITH BELTS.**—Experiments on the amount of power that can be transmitted by a belt of given size show many discrepancies, and to this circumstance are due many of the difficulties encountered in connection with the subject. These discrepancies, it seems, arise from the fact that belts of different qualities are often experimented upon, and it is pretty well settled that, while rules can be constructed that will show what power a good belt may transmit under given conditions, they cannot be implicitly relied upon to show how much power a particular belt does transmit. A question of this kind can be answered only by experiment, although the rules may frequently enable an experienced mechanic to gauge the result in advance with a fair degree of accuracy. —*Iron*.

**HOW LONG OUR COAL WILL LAST.**—The following interesting figures, indicating the length of time the anthracite coal supply of Pennsylvania may be expected to last, have just been compiled. The total anthracite area before mining commenced was 320,000 square miles. Allowing 1000 tons to the acre, a foot in depth would give 320,000,000 tons. Assuming that the depth averages 30 feet, it gives a grand total of 9,600,000,000 tons. At the present time the consumption averages about 30,000,000 tons a year. So it will be seen that at the commencement of mining operations the supply was sufficient for 320 years. About 508,000 tons, or about 17 years' supply, have been mined, leaving sufficient to supply the demand for over 300 years to come. —*Philadelphia Times*.

**LARGE LOCOMOTIVE WHEELS.**—There has been for some time an inclination to increase the diameter of locomotive wheels to secure increased speed. They have for some time been growing larger and larger. The largest yet built is a mammoth engine for one of the French roads. This locomotive has six coupled wheels 8½ feet in diameter. The tender and coaches are to have wheels of the same dimensions, and the calculation is that with such a train a speed of from 72 to 78 miles an hour can be obtained. The coaches will be swung inside and between several pairs of wheels.

**IMPROVED MANIPULATION OF NATURAL GAS.** Manufacturers who are depending largely on natural gas, and those who expect to be provided with it at a long distance from the wells, have been, within two or three days, interested in the announcement of a patent which will carry it safely any desired distance. It is a process of mixing air with gas in such proportions that, while the danger of explosion is taken away, all the heating quality still remains. It will also leave the air of the rooms in which it is used in a healthy condition. —*Pittsburg Times*.

**STEEL NAILS.**—Establishments for the manufacture of steel nails and steel-nail plates are on the increase in this country. These nails, it is alleged, are produced much more cheaply than those of iron, owing to the cheaper process—the Bessemer—in preparing the metal, but their grip is less than that of iron nails.

## SCIENTIFIC PROGRESS.

## Meteors and Their Scientific Value.

We are all more or less familiar with the heavenly visitants to our earth commonly known as "shooting stars." As a general thing these visitants are completely vaporized on coming in contact with our atmosphere, or reduced to impalpable dust by its friction. They are always visible, in greater or less numbers, every clear night, and sometimes they appear in almost innumerable numbers.

These bodies are similar in constitution to "aerolites" or "meteorites," the only difference being in their bulk. When one is of sufficient size to withstand the frictional action of the atmosphere and reach the earth it is called an aerolite. These bodies, no doubt, move about in the heavens much like comets—indeed they are generally supposed to be fragments of comets. Biela's comet presents a notable instance of such disruption. It is now represented only by a stream of meteors, which follows what was once that comet's path.

The bottom of the ocean in many places seems to be covered with meteoric dust—the finely-divided fragments of meteors which have fallen upon the sea. There is said to be a region of the sea between Honolulu and Tahiti, where the ocean is about two and one-half miles in depth, where the sea bottom is completely covered with this dust, as is proven by the material which the lead brings up when soundings are taken along this region. Falling upon land, this pulverized material is not distinguishable from its intimate mixture with the ordinary soil, but the accumulation of centuries in sea depths forms a wondrous story, which is read and studied with interest by the scientist.

Meteors vary very considerably in their constitution and make-up, and furnish to the scientist very clear evidence of the composition of other heavenly bodies than our own. Analysis shows that they do not bring with them any mineral which is not found upon the earth. Some 22 elements have so far been observed in the process of analyzing these foreign bodies, among which iron, magnesium, nickel, sulphur, phosphorus and carbon are the most prominent. Meteors vary very considerably in their character, as do minerals upon the earth. They have been carefully classified and divided into four classes or groups, based upon the proportion of iron which they contain.

Those of the first group constitute what is known as meteoric iron, which is always alloyed in nearly the same proportions with nickel and a few other metals. It is of a steely character and extremely hard. Meteoric iron is always recognizable by a singular peculiarity of structure. If a polished surface is moistened with an acid, numerous straight lines appear, crossing each other at various angles, forming a network of geometrical figures, as regular and clean cut as if made with an engraver's tool. These lines are known as Widmanstaetten figures, so named from the man who first discovered them. They result from the fact that the metal is not homogeneous, and that it is crystalline in formation. Meteorites of this description are called *holosiderites*—or all iron. They are much more rare in occurrence than either of the other groups.

Another variety consists chiefly of silica in combination with magnesia and peroxide of iron. If these silicates are in small proportion and thinly scattered through the mass, they are known as *syssiderites*.

Meteorites in which the iron is in relatively small proportion, appearing only in isolated grains, are called *sporadosiderites*.

There are a very few meteorites in which no metallic iron occurs. Such are called *asiderites*. They are usually of a dull black color, stony in character, and in appearance much like peat or lignite. They contain carbon in combination with hydrogen and oxygen. It is in this class of meteorites alone where any hope has been indulged of finding the remains of organic or animal beings, but thus far the most careful examination has failed to reveal anything of the kind. Even if such had existed, the intense heat excited while passing through the atmosphere would no doubt have obliterated all traces of the same by reducing them to their purely earthy or mineral condition.

Meteors have for many years formed a most interesting study, and are always of intense interest to even the casual observer. Many are known to be of immense size, and it is a most interesting, not to say alarming, fact to reflect that such huge masses are constantly moving about in space with incredible velocity and at all times liable to come in contact with the earth. Where they originated or how they came to exist in such vast numbers, as is evidenced by the earth encountering them by hundreds and thousands every few hours, in every portion of its orbit, is a question of great interest. Their existence forms a wondrous story in heavenly lore, and their continuous bombardment of our mundane sphere a theme of constant interest to its inhabitants.

**THE ORIGIN OF MAN.**—It is generally thought that Darwin suggested that man was descended from the monkey. But such is far from the fact. What Darwin's hypothesis suggested was, not that man was descended from the monkey, but that both man and the monkey may be descendants of a common progenitor, a common type, now extinct, and of which no indisputable traces have yet been found. From

this common type, or ground form, so to speak, the process of development may, according to Darwin, have resulted in two distinct branches or offshoots—the one branch of development ending in the monkey tribe, the other branch ending in man.

**THE EARTH AS A TIME-KEEPER.**—A problem which is attracting to its study astronomers, relates to the earth as a time-keeper. We measure time by dividing either the period during which the earth revolves around the sun, or that in which it turns on its own axis. By the first method we measure a year; by the second, a day. The earth, according to some astronomers, is losing time. Through two causes, the sun's attraction and the friction, so to speak, of the tides, the earth each year revolves more slowly on its axis. The speculative question which these astronomers are discussing is whether in the end the earth will stop its revolution upon its axis, and will present always the same face to the sun. When that event occurs, there will be perpetual day in one part of the earth, and perpetual night in another. But there is no occasion for immediate alarm. The rate at which the earth is supposed to lose time only shortens the year by half a second in a century. There are more than 31,500,000 seconds in a year. Therefore, if the earth ever does cease to revolve on its axis, it will be more than 6,000,000,000,000 years before it will stop.

**THE WORLD MUST MOVE.**—In 1877, electric lighting by the incandescent system was declared by many to be contrary to scientific principles. The same was said of the use of iron, and later, of steel, in bridge building. The Suez canal was once denounced as a wild and foolish scheme. Less than 50 years ago educated mechanics asserted that steamships could never carry enough coal for a long voyage. Leading ship-builders told us that iron ships could not swim, and when one or two floated it was said that they would not hold together permanently. Rolls for flour making were once hooted and derided. The world will not stand still for any one.

**EXTINCTION OF RACES.**—Attention has lately been called to two races of men that must soon become extinct. At the present rate of decrease, the Moors, of New Zealand, now reduced to less than 40,000 from 100,000 in Capt. Cook's day, must have disappeared by the year 2000. The Laplanders are estimated to be 30,000 in number, and are gradually becoming fewer. To the above might be added the North American Indians, who are rapidly growing fewer, and the time is probably not far distant when they will entirely disappear from this continent and the world.

**PHOSPHORIC ACID FROM SLAG.**—Prof. Scheibler, of Berlin, has invented a process for the production of phosphoric acid from the slag made in the Thomas-Gilchrist method. The slag, having been roasted in an oxidizing flame, is pulverized and sifted. The powder is dissolved in hydrochloric acid and the solution saturated with lime-water. The resulting product contains from 35 to 37 per cent of phosphoric acid in the form of bibasic phosphate of lime, and a second roasting yields a substance in which the content of phosphoric acid is as high as 45 per cent.

**THE FLOWERING PLANTS KNOWN TO BOTANISTS.** says the *New York Independent*, are, in round numbers, about 100,000 species, but it is not improbable that, by the time all the recesses of the earth have been explored, the number will be largely increased, if not, perhaps, doubled. The whole interior of China is, so far, comparatively unknown; and, so far as the borders are occasionally penetrated, continually gives new species.

**AN ELECTRICAL TREE** has been found in New Guinea by two German explorers. When the explorers reached a spot 12 days distant from the coast they found their compass useless, owing to the presence of a tree which so completely possessed the properties of a highly charged electric battery that one of the travelers was knocked down when he touched it. Analysis showed the tree to consist of almost pure amorphous carbon, and it has been named *elsassia electrica*.

**MILDEW DESTROYER.**—Sulphide of potash has proved in our practice all that has been claimed for it by the English press as a destroyer of mildew on roses, chrysanthemums and some other greenhouse plants. A quarter of an ounce dissolved in a gallon of water and thrown on the affected foliage with a fine rosed syringe will wholly destroy the fungus, and the leaves will not be injured. —*Vick's Magazine*.

**THE FLIGHT OF SWALLOWS.**—An experiment was made at Pavia, in Italy, with two swallows, to determine their speed. Two hen birds were taken from their broods, carried to Milan and there released at a given hour. Both made their way back to their nests in 13 minutes, which gave their rate of speed at 87½ miles an hour.

**THE DETONATION OF METEORS.**—Signor Bombicci supposes the detonation of meteors to be that of an explosive gas formed during the surface heating of the mass in the atmosphere, and accumulating chiefly in the vacuum space left behind the mass in its very swift flight.

## Mono Lake Water.

At the last meeting of the San Francisco Microscopical Society much interest was excited by the exhibition of some collections of animal and vegetable life found in and around Mono lake by Dr. H. W. Harkness during his recent trip to that locality. Notable among the latter class were specimens of the rare bacterium which has been provisionally classed as *Bacterium rubescens*, although Dr. Harkness believes there are strong grounds for regarding it as specifically new. It is found in immense quantities in Mono lake, and aggregated masses of it are of a beautiful rose color. It seems to have both a still and a motile stage. No spore formation has been discovered in the preliminary examinations, but culture experiments are now being carried on, which will no doubt disclose its complete life cycle. Numerous very active infusoria were found associated with the bacteria, and Dr. Harkness reports having found many species of diatoms, some aquatic insect larvae, minute crustaceans, and also fresh-water algae, in this remarkable lake, the water of which is so intensely alkaline that it was formerly thought incapable of supporting either animal or vegetable life. An official analysis of the water of the "Dead Sea of California," as it has been called, has just been received from Washington and is as follows:

Silica.....	0.28
Chloride of potassium.....	2.23
Chloride of sodium.....	18.22
Sulphate of sodium.....	10.07
Borate of sodium.....	.20
Carbonate of sodium.....	10.49
Carbonate of calcium.....	.68
Carbonate of magnesium.....	.36
Water.....	948.47

Total.....1,000.00

Thus showing the remarkable proportion of nearly 52 parts of solid constituents in each 1000.

Specimens were also shown of the evaporated alkaline sediment from Owens lake, stained a bright red by the presence of enormous numbers of the above-mentioned bacterium. Some further communications regarding the flora and fauna of the Mono lake region have been promised by Dr. Harkness.

## Gold in Madagascar.

Mr. Baron, one of the London Missionary Society's agents, has carefully studied the geology of the inland provinces of the African island. He states that the Malagasy Government has recently obtained gold from Ampasiria, a place about half-way between the villages of Malatsy and Mevatana, on the road to Mojanga from the capital. From this last-named place there is navigable water communication to Mojanga (90 miles). The valley of the Ampasiria is in the district north of Malatsy, and south of the confluence of the Ikopa with Botsiboka rivers, and is one of the numerous similar dales lying between hard clay ridges, sprinkled with quartz gravel. In these green valleys are groves of rofia palm, bamboo canes, and a species of fig-tree called adabo. Overlooking this happy valley on the north is the high named Kalomainty, at an elevation of 1290 feet above the sea. On the south side it is bordered by another ridge, beneath which flows the river Andranolite, entering the Ikopa just above the great rapids; another locality, where gold is found in the bed of a stream, has been indicated at Itompoanandrariny, west of Valalafotsy, at an elevation of 4480 feet, close to the watershed between the western and northern river systems, and north-west of the volcanic area of Ifanja and Itasy. Yet even close to Antananarivo, at Tanjombato, within a mile or two south of the capital, has gold also been detected, and perhaps in other localities as well. The gold is of excellent quality, but at present the native laws are very stringent in forbidding not only the sale but the search for the precious metal, as the Government wisely retain the monopoly of working the ore. Nevertheless, by no means does all the gold found reach the national treasury, and it is said that gold nuggets are smuggled out of the country in the cakes of caoutchouc and gums collected in the forests nearer the coast.—*London Mining World*.

**CONCENTRATOR FOR BLACK SAND.**—Messrs. Wm. A. Woods and C. C. Garcelon, of this city, have invented what is known as a centrifugal concentrator, a contrivance for separating gold from crushed rock or sand. A patent has been secured on this machine, which has required a year of study and labor in its construction, and is a success. Last week the machine was in operation at the residence of Mr. Wood, on Ocean View avenue, and out of 400 pounds of black sand, hauled from the Aptos beach, \$3 in gold was taken. It is estimated that in one ton of this sand from \$5 to \$10 can be taken out, and the concentrator is capable of running through 25 or 30 tons per day. It will be taken to Aptos and put in operation.—*Santa Cruz Sentinel*.

**THE AIR OF THE SEA.**—The air of the sea, taken at a great distance from land, or even on the shore and in ports where the wind blows from the open sea, is an almost perfect state of purity.

## USEFUL INFORMATION.

## Importance of Practical Education.

A correspondent of the *Atlanta Constitution* makes some suggestions in a plain but practical way, which are good for both boys and men to bear in mind. We quote as follows: I believe in schools where boys can learn trades. Peter the Great left his throne and went to learn how to build a ship, and he learned from stem to stern, from hull to mast, and that was the beginning of his greatness. I knew a young man who was poor and smart, and a friend sent him to one of these schools up North, and he stayed two years and came back as a mining engineer and a bridge builder, and last year he planned and built a cotton factory, and is getting a large salary. How many college boys are there in Georgia who can tell what kind of native timber will bear the heaviest burden, or why you take white oak for one part of a wagon and ash for another, or what timber will last longer under water and what out of water? How many know sandstone from limestone, or iron from manganese? How many know how to cut a rafter or brace without a pattern? How many know which turns the fastest—the top of a wheel or the bottom—as the wagon moves along the ground? How many know how steel is made, and how a snake can climb a tree!

How many know that a horse gets up before and a cow behind, and the cow eats grass from her, and the horse eats to him? How many know that a surveyor's mark on a tree never gets any higher from the ground, or what tree bears fruit without bloom?

There is a power of comfort in knowledge, but a boy is not going to get it unless he wants it bad, and that is the trouble with most college boys, they don't want it. They are too busy, and haven't got time. There is more hope of a dull boy who wants knowledge than of a genius, for a genius generally knows it all without study. These close observers are the world's benefactors.

**SINGULAR USE FOR ELECTRICITY.**—A savant named Henri Roget, hailing from Lyons, has, it is stated, a new use for electricity. He has a patent to apply it as a substitute for the cat-o'-nine tails in corporeal punishment. The culprit, having been undressed, is securely strapped to a steel triangle, which is connected with one pole of a powerful battery. The other pole is connected with the whip, which consists of a number of steel wires covered with a sponge. This whip is dipped in water before the stroke is administered and wherever the wet wires touch an electric discharge takes place. The inventor claims that the chastisement can be made so mild as not to injure a schoolgirl, while, on the other hand, by increasing the power of the battery, a punishment can be administered beside which the knout would be mere child's play, and at the same time no injury is inflicted, the disgusting spectacle of a lacerated back is avoided, and the culprit, instead of having to be sent to the hospital to have his wounds healed, can be put to work in five minutes after the flogging is over. M. Roget intends petitioning Gen. Boulanger, the French Minister of War, to allow his patent to be used experimentally on the next soldier sentenced to the cat. Flogging is not in existence in the French army, nor is it likely to be introduced to test the machine.—*Electrical World*.

**TO PREPARE AN IRON CASTING FOR A PATTERN.**—The *Manufacturer and Builder* suggests the following: To properly prepare an iron casting of any object to serve as a pattern has been the subject of considerable experiment. The method of procedure is varied, according to the size of the object to be reproduced. Large iron patterns are generally pickled in the usual way, and then are well sand-papered, and one or more coats of varnish applied. Small iron patterns must first be pickled; when dry, a coating of sal-ammoniac water is put on them to rough the surface. They are then well sand-papered and heated, so that wax will run freely on them. After the surface has been covered with wax, remove the surplus and rub the balance well into the surface with a piece of cork. For very fine castings, "Bayberry wax" is preferred. On brass casting spermaceti wax is the best.

**A NEW FIRE DANGER.**—Fire originating from heated asbestos intended as sheathing is noticed by a patrol inspector in Philadelphia. In one of two recent instances the combustion chamber of a regenerative gas lamp was too near certain woodwork, and asbestos was inserted between, but the heat soon penetrated the stratum of asbestos and set fire to the wood. In the other case the sheet-iron top of a portable heater was within a few inches of the joists of the first floor; asbestos was placed on the heater, but heat passed through and the joists took fire. Heat was always above 300° F., and confined. No fires were noted from steam-pipes sheathed in asbestos. The inspector recommends as a safeguard from the heating of the non-inflammable fibrous stone an unobstructed air current between the source of the heat and the asbestos covering.

**HOW TO PREVENT THE RESTING EAST OF SCREWS.**—A method which will, it is said, be found quite effective against dampness, either inland or on the seacoast, is to dip the screws, before putting them in place, in a paste formed

of a mixture of oil (or grease) and fine graphite. This mixture will certainly be much more effective than the use of the fat alone; but in any case where a machine is much exposed, especially to salt air, the screws should be occasionally removed—say once a year—and returned to their places after making a fresh application.

**FOR CEMENTING IRON.**—The following recipe for cementing iron is given by an English mechanical journal: Take equal parts of sulphur and white lead, with about a sixth of borax; incorporate the three thoroughly. When about to apply it, wet it with strong sulphuric acid and place a thin layer of it between the two pieces of iron and press them together. In five days it will be dry, all traces of the cement having vanished, and the iron will have the appearance of having been welded together.

**PAINT FOR IRON.**—A cotemporary throws out the following suggestion: "Required to produce a perfect paint for the preservation of iron and steel. It must have a high mechanical adhesive property, and be composed of material electro-negative to iron and mixed with some tenacious fluid vehicle containing no oxygen, if possible, and not liable to be decomposed by the iron beneath." Inventors would do well to give the subject their consideration.

**THE BIGGEST BUILDING IN THE UNITED STATES** will be the City Hall of Philadelphia, now in process of construction. Between \$11,000,000 and \$12,000,000 have been expended upon it since 1872. It is estimated to cover 2800 more square feet than the Capitol at Washington. The tower on the north side will be surmounted by a statue of Penn., and its extreme height when completed will be 535 feet. It has now reached a height of 270 feet.

**ARTIFICIAL WHALEBONE.**—The scarcity of whales is seriously felt in reducing the supply of whalebone, which has advanced several times its price of a few years ago. To meet this deficiency several substitutes have recently been introduced; the latest is a mode of producing a substitute for the quills of geese and turkeys. A factory has recently been put in operation in Michigan to furnish the article.

**TO SILVER IRON.**—One of the most ingenious processes which have lately come into vogue in the treatment of iron—an Austrian invention—is that of giving to the metal a silver surface, this being effected by first covering the iron with mercury and then silver by the galvanic process. By heating the iron to 300° C. the mercury evaporates and the silver layer is fixed.

**WHAT NATURAL GAS HAS DONE.**—Since the introduction of natural gas into Pittsburg, Pa., the output of the mills and factories has been increased 20 per cent, a large number of new plants have been erected, and nearly 10,000 additional men have been given employment.

## GOOD MEALTH.

## Food.

Our bodies are made of what we eat.

An article to be suitable for food must contain at least one of the elementary substances of which the body consists, and this must be capable of a ready separation from all other elements. The latter, if not poisonous, will be rejected from the system without harm.

The best kinds of food are such as contain the most of the bodily elements. Milk contains all, and is hence a perfect food.

A proper diet is such a combination of articles as together furnish all the elements in due proportion, while at the same time these articles please the taste and gratify our love of variety. Starvation would result in time if a single one of these elements were lacking. Not only must muscle, bone, etc., be provided for, but, still more, brain, nerve and every secretion.

The modern fancy for the whitest bread is at fault, for such bread is deficient in the elements that make brain, nerves and bones. Hence the tendency to nervous diseases, dyspepsia and decaying teeth. Absence of vegetable food gives rise to scurvy; the too exclusive use of animal food to gout.

But food must be digested. For this no less than five digestive fluids are secreted by appropriate glands—saliva, for starch and sugar; gastric juice, for flesh, fish, eggs, etc.; bile and pancreatic juice, for fat, the latter also aiding in the digestion of starch; and the intestinal secretions, to complete the process. A deficiency in any one of these results in some form of dyspepsia.

The digested food must pass from the intestines into the circulation. Hence myriads of hungry mouths seize it from the former and pour it through countless minute vessels, which constantly unite and form larger, into the right side of the heart. Should these vessels be closed up by inflammation the body would waste away, however good the appetite and vigorous the digestion.

This imperfect blood does not, however, yet go into the full circulation, but passes round through the lungs with the venous blood and then into the left side of the heart, whence it is sent out into the arteries a pure fluid, rich in every element.

But the process of nutrition is not yet finished.

Those sleepless workers, the ultimate cells, whether of brain, or bone, or muscle, or membrane, throwing off each moment the waste debris, take from the same arterial fluid each what it needs.—*Ex.*

**SOFT, WHITE HANDS.**—A woman, whose pretty hands are being ruined by washing in hard water, writes to *Good Housekeeper's* to ask a remedy. That journal answers: "Water can be easily softened with a few drops of ammonia, or, what is better, a small piece of lump borax. Warm water into which enough borax has been dissolved to make the water feel a little slippery, when pressed between the thumb and finger, is very good for washing the hands. Hands kept dirty are never smooth and white. Absolute cleanliness is necessary. Many people who do not work wash their hands but seldom. The day's accumulation of dirt is allowed to remain on the hands at night. Upon rising the hands are washed in cold water. The possessor wonders why, when she does no work, her hands do not look any better, if as well, as her chambermaid's. The hands should always be washed in warm soapsuds before going to bed. White soaps are safest. Highly scented and colored soaps are almost invariably made from rancid and ill-smelling fats. After the hands are thoroughly dried, use a few drops of mixed glycerine and camphor, which the druggist can prepare for you. Drop into the palm of the hand and rub on the hands. This will be all that will be necessary to show decided improvement."

**INOCULABILITY OF YELLOW FEVER.**—The Brazilian doctor whose discoveries in inoculation for yellow fever were recently alluded to in this column, according to the *London Lancet*, seems to have a rival in Havana. The *Lancet* says: Dr. Carlos Finlay, of Havana, has published the results of several experiments he has made on the inoculability of yellow fever. He performed the operation, or rather got it performed for him, by mosquitoes, which he caused first to sting a patient suffering from yellow fever and shortly afterward a healthy person who was to be (with his own consent, of course) the subject of the experiment. He found that the disease was only inoculable from the third to the sixth day. When two mosquitoes were employed, so that a double dose was given, the symptoms of the experimental disease were somewhat more severe than when only a single mosquito was used. Of 11 cases of inoculation, six were efficacious, one doubtful and four negative. The period of incubation varied from 5 to 14 days; the symptoms consisted of headache, pyrexia, injection, with sometimes an icteric tint of the conjunctiva, and in some cases albuminuria. The fever lasted, as in the ordinary form, from 5 to 21 days. The author believes that this method of producing artificial yellow fever will ultimately be found very valuable as a prophylactic against the natural and dangerous form of the disease.

**STRANGELY POISONOUS LIZARDS.**—The heloderma is the only poisonous lizard in the world, as far as known, and is confined to Mexico, Lower California and Arizona. The common name is the Gila monster. The poison comes from poison glands and the teeth are channelled to accelerate its passage into the wound. Brandy and whisky are generally antidotes to rattlesnake poison, but fail in the case of a bite from this reptile. The poison of the heloderma is entirely different from that of a snake. The latter kills by paralyzing the respiratory center, while the poison of the Gila monster paralyzes the heart. Experiments have been made showing that subcutaneous injections cause no local injury, while the action of the heart was seriously affected, becoming slowly contracted, while the spinal cord is paralyzed.—*Salt Lake Tribune*.

**DENGUE FEVER.**—At the recent meeting of the State Medical Association of Texas, Dr. McLaughlin, of Austin, read a paper claiming that he had made a remarkable discovery in regard to dengue fever. He claims to have found the microbes of the disease, and from his experiments he believes that the same discoveries are to be made in small-pox, yellow fever, hydrophobia, hog typhus, chicken cholera and Texas cattle fever, all of which can be mitigated or avoided by vaccinating with attenuated virus.

**IMAGINARY ILLS.**—A Philadelphia physician says that a great deal of what passes for heart disease is only mild dyspepsia; that nervousness commonly is bad temper, and that two-thirds of so-called malaria is nothing but laziness. Imagination, he says, is responsible for a multitude of ills; and he gives, as an instance, the case of a clergyman, who, after preaching a sermon, would take a teaspoonful of sweetened water and doze off like a babe, under the impression that it was a *bona fide* sedative.

**ANTIDOTES FOR CERTAIN POISONS.**—It is said that a standing antidote for poison by poison-oak, ivy, etc., is to take a handful of quicklime, dissolve in water, let it stand half an hour, then paint the poisoned parts with it. Three or four applications, it is said, will cure the most aggravated case. Poison from bees, hornets, spider bites, etc., is instantly arrested by the application of equal parts common salt and bicarbonate of soda, well rubbed in on the place bitten or stung.

## MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

## CALIFORNIA.

## Alameda.

**OPENING A COAL MINE.**—Livermore *Herald*, June 8: Jenkins Richards is engaged in running a drift north on the Fortuna vein between Nos. 1 and 2 veins six feet. Vein in the face looking better than at last report. In winze 135-foot level we have been contending with bad air most of the week. Have overcome the trouble, however, and made an advance of four feet.

**THE STANDARD CON.**—Number of men employed in and about the mine: Engineers, 2, pumpman 1, shift bosses 1, carpenter 1, blacksmith 1, miners 24, stationmen 4, carmen 5, timbermen 1, laborer 1; total employed, 41. Ore bodies without special change. Mine closed from Monday, 5th, until Tuesday, 6th, A. M., since which time work has been steady at both. Ore shipped to mill during week, 266 tons.

## Amador.

**QUARTZ PROSPECT.**—Amador *Ledger*, July 10: Hugh Mason is opening up a promising quartz prospect, located about half a mile west of the Downs mine, near Volcano. He is running a tunnel into the side hill, a distance of 60 feet, showing a well-defined quartz ledge containing gold in good paying quantities. T. Gillick started his mill last week on from 75 to 100 tons of exceedingly rich ore, which he had accumulated on the dump. The Volcano Gold Gravel Co. have made no thorough cleanup as yet this season. The partial cleanups of the bedrock have been much more satisfactory than in previous seasons, and the opinion is general that the surrender of gold this year will reach paying figures. At the Tellurium at Pine Grove the pump has been taken out of the shaft and other machinery packed up ready for shipment. The mill has been running lately, finishing up a small quantity of ore on the dump. The indications point to the complete abandonment of active operations by the present company. At the Downs mine the work of putting in the pumps is still in order. It will be perhaps another month before sinking will be commenced. The St. Julian at Middle Bar has come to a standstill. In upraising to make connection between the tunnel and winze a lack of funds necessitated a suspension of operations for an indefinite period. The shaft of the Zeile mine is being deepened. The capacity of the reservoir is also being increased by a thorough cleaning out of the sediment which has been accumulating for over a year past. Drifting for the ledge is still the work in hand at the Moore mine.

## Calaveras.

**IRON.**—Mt. Echo, July 9: There are, perhaps, few persons who are aware that there is one of the most extensive iron mines in the State within less than a mile of Murphy, in this county. It is the property of J. L. Sperry, owner of the celebrated Big Tree Grove. This property will be valuable some day.

## Contra Costa.

**STEWARTVILLE.**—Cor. Concord *Sun*, July 10: The future prospect of our mines is bright. A large body of coal on the west side, that was supposed to have been worked, is found to be untouched.

## El Dorado.

**THE O. K.**—Georgetown *Gazette*, July 8: We visited Dr. Spencer's mine, the O. K., last Tuesday, finding his sons Cad. and George at the windlass and Ad. Porter in the shaft, all busy handling ore which will mill \$10 to \$12 per ton, about 80 tons of which is already on the dump. The shaft is upward of 40 feet in depth, and the lode is about 10 feet wide, and prospects very evenly throughout. It is noticed that the ore improves in richness as they go down. We made several tests with the pan, both from the dump and from ore we took from the ledge while in the shaft, and we can assure all who have not visited this mine that Dr. Spencer has a mine which, if the ore body continues to extend and prospect as well for the next 100 feet, will prove one of the best mines in California. George Handy is furnishing the Taylor mine with lumber, of which a large amount will be used. The State Mountain mine mill is busy as ever turning out handsome dividends for its lucky owners.

## Fresno.

**CLEANUP.**—Fresno *Expositor*, July 9: It is stated on good authority that the last cleanup of the McNally mine amounted to about 90 pounds of gold, and that about \$48,000 have so far been extracted from the mine in two runs. It seems too bad that the Hildreth mine, an equally good property, could not be gotten into energetic hands and developed as it should be.

**MUSICK.**—Fresno *Republican*, July 9: At last reports the owners of the Musick mine, about 12 miles from here, had, as the saying is, "struck it rich." At present they are working two shifts, three men in a shift. They have an incline down 120 feet, and are running a double tunnel. The ore averages from 7 to 15 inches thick, and assays about \$65 per ton, although by the arastra process only about \$25 per ton is obtained from it. The hoisting works are run by horse power. J. J. Musick's family moved up to the mine about two weeks ago.

## Mono.

**THE CON. PACIFIC.**—Bodie *Miner*, July 12: In drift north on the Fortuna vein between Nos. 1 and 2 veins six feet. Vein in the face looking better than at last report. In winze 135-foot level we have been contending with bad air most of the week. Have overcome the trouble, however, and made an advance of four feet.

**THE STANDARD CON.**—Number of men employed in and about the mine: Engineers, 2, pumpman 1, shift bosses 1, carpenter 1, blacksmith 1, miners 24, stationmen 4, carmen 5, timbermen 1, laborer 1; total employed, 41. Ore bodies without special change. Mine closed from Monday, 5th, until Tuesday, 6th, A. M., since which time work has been steady at both. Ore shipped to mill during week, 266 tons.

## Nevada.

**PENNSYLVANIA MINE.**—Foothill *Tidings*, July 9: The Pennsylvania Con. quartz mine is situated on Kate Hays Hill, and is a parallel lode to the Empire mine, and in all of its characteristics closely resembles that remarkable property. It is provided with good hoisting and pumping machinery, and the incline shaft is sunk to a depth of 240 feet. Only one level has been opened and this at a depth of 175 feet. This level has produced considerable good ore that has milled from \$25 to \$30 per load. The lower level is now being opened and an air chute from it to the upper level run on the trend of the ledge was completed yesterday. In running this chute some quartz was found worth from \$20 to \$30 a pound, and from all appearances the Pennsylvania, or Penn. Con., as it is called, will soon be a regular dividend payer. Being below the Empire, in the same ridge, it can be easily worked by water-power, which adds still more to its value as a property.

## Plumas.

**BIG FLAT MINES.**—Greenville *Bulletin*, July 7: The mines that have been opened on Big Flat are yielding large returns, considering the force employed. About a year ago work on the Glazier commenced. A great deal of the time was spent in opening the mine, yet during the period named over \$11,000 has been taken out. In June three men were employed in drifting and extracting gravel. For the month \$1700 was realized. A great deal of the gold is very coarse, some of the pieces weighing more than an ounce. In the drift claim owned by Messrs. Ellis, Firststone and Bressler, work has been progressing very satisfactorily. We learned that they have proceeded across the channel 100 feet without reaching the opposite rim. The bed of gravel is large, easily worked, and pays well, though figures have not been given us by the parties interested. It is safe to say that it is paying \$20 to the man.

## San Bernardino.

**STRUCK IT RICH.**—Calico *Print*, July 8: We reckon that George Silveria and Frank Williamson are two of the happiest men now living in San Bernardino. Some time since Mr. Silveria went to Holcomb valley, where he and Mr. Williamson have a placer mine and a quartz ledge. This morning a reporter was shown four nuggets, weighing \$20, taken from this placer mine, and specimens of quartz from their ledge that showed large blotches of gold. To say that Silveria and Williamson are happy would give but a faint idea of their feelings. They have struck it, and it is rich.

**THE MORONGO PASS MINES.**—Los Angeles *Herald*, July 9: Judge J. G. Nichols arrived yesterday from a pleasant prospecting trip in the Morongo Pass, about 30 miles east of San Bernardino. The judge says there is plenty of water and timber in the mountains, and plenty of gold that can be had by the outlay of enough capital to erect machinery and open the mines. Probably no person has ever prospected Morongo Pass as thoroughly as Judge Nichols. Many years ago he was driven out of the Pass by the Indians, and all his personal property and cabin burned by them. These natives are now in the mountains along the Colorado, and no disturbance is likely to arise again from that source. Holcomb valley he also pronounces as very rich, and predicts that great mining enterprises will soon be in active operation in that region and in Bear valley.

**PLACERS.**—San Bernardino *Index*, July 9: Geo. Silveria and Frank Williamson some time since went to Holcomb valley, where they have a placer mine and a quartz ledge. A reporter was shown four nuggets, weighing \$20, taken from this placer mine, and specimens of quartz from their ledge that showed large blotches of gold.

## San Diego.

**NEW MILL.**—San Diego *Sun*, July 9: D. R. Frankel, of San Francisco, one of the proprietors of the Owens mine, near Julian, reports that the new 10-stamp mill was put in active operation on last Saturday. Twenty-five men find employment in the mine, and all indications are flattering for an excellent run. Mr. Frankel left for home on the Santa Rosa this evening.

**JULIAN AND BANNER.**—San Diego *Union*, July 9: In a brief interview with Mr. Milton Santee yesterday, we gleaned some facts and opinions that will possess interest for our readers. The gentleman referred to has recently returned from a trip to the Julian country. The party traveled by way of El Cajon to the Stonewall mine near Julian, where they tarried for some time inspecting that mine and others in the vicinity. The character of the Stonewall as a paying mine is well established. The last milling yielded \$39 per ton. There is a large body of ore and every evidence that it will increase in richness as it has been doing ever since the owners have been working it. It is an easy mine to work. It is claimed that there is much mineral wealth in that country which will ultimately be developed. From the Stonewall mine the party proceeded to Julian. In looking over the hills near this town, Mr. Santee picked up a piece of quartz which showed so much gold that he staked a claim at the place of finding. The quartz was brought to the city, and on being assayed yielded at the rate of \$411.33 1/2 to the ton. Other samples have been sent to an assayer at San Francisco. The fine timber in the Julian country excited Mr. Santee's admiration. It is a beautiful country in summer. The forests of oak and pine make ample shade, and the ground is carpeted with green grass. The timber will furnish sufficient fuel for mining purposes for many years.

## San Luis Obispo.

**CHALK ROCK.**—Cor. San Luis Obispo *Tribune*, July 9: Messrs. Jas. Sheerer & Co., of San Francisco, who are running the Tar Springs Asphaltum Mines, have begun the shipment of chalk-rock from Arroyo Grande, which will be used to mix with the asphaltum for paving purposes.

## Shasta.

**THE TELLURIUM MINE.**—Shasta Co. *Democrat*, July 8: Mr. Scheerer has at last closed arrangements with Mr. D. L. Calahan for erecting reduction machinery on the Salt creek tellurium mine. The machinery consists of a roaster of a daily capacity of ten tons, settlers, amalgamating pans, etc. The material for the roaster was ordered last week, and a San Francisco foundry is getting up the machinery. Mr. Calahan writes that there will be no further delay, and that the plant will be completed as speedily as possible.

**SQUAW CREEK ITEMS.**—The latest news from Squaw Creek is cheering. At the Snyder mine three eight-hour shifts are driving the main tunnel ahead about six feet per day in a fine body of rich sulphurets; the quartz also shows up finely in free gold. They now have a pay chute about 160 feet in length with nearly 200 feet of backs. At the Clipper they crosscut the ledge 78 feet from the mouth of the tunnel and show very high grade of ore 28 inches wide, and are still driving ahead the main tunnel. At Riley, Mathews & Co.'s both mills were shut down last week to make necessary repairs and give the boys a show to celebrate. They started up again yesterday full handed. At the Balacalla, Ellis & Murray are facing up for a new tunnel. This is undoubtedly one of the finest mining properties in Northern California; a few dollars judiciously expended would give it the boom it really deserves.

## Sierra.

**A \$7000 NUGGET.**—Sierra *Tribune*, July 9: Dick Steelman and Phil Hayes' drift mine is located about 15 miles north of Sierra City, in Gold valley. This has always been supposed to be a good-paying mine, but just what it yields no one but those directly interested seems to know. A *Tribune* reporter has heard, on what he considers reliable authority, however (in fact, there is no doubt about the truthfulness of the report), that one of the largest gold nuggets ever discovered in the State was found in that mine last week. This huge specimen, with the quartz that clung to it, weighed 37 pounds, and the solid gold alone tipped the scales at 32 pounds—amounting to about \$7000. The nugget was brought to town last Saturday evening. The matter was kept a secret so far as possible. Five years ago a chunk of gold valued at \$2200 was picked up in these same diggings.

**THE OSCEOLA MINE.**—T. H. Smith, the owner of the Osceola mine, near Alleghany, was in town Monday. Mr. Smith has engaged the Downieville foundry to erect a Forbes mill at the mine. He has about 2000 tons of quartz on the dump, which competent judges estimate will yield over \$30 per ton. Mr. Smith was recently offered \$50,000 for his mine, but only laughed at the proposition and said that three times that amount would not "touch the mine." He was then asked to set his price, but refused to, saying that he did not want to sell. Mr. Smith has pounded out enough gold with a hand-mortal to pay all his expenses.

**THE SUNFLOWER MINE.**—Sierra *Tribune*, July 9: The Sunflower quartz mine is located about 2000 feet south of the Alaska mine, at Pike City. We are informed that the company has obtained sufficient results to justify it in erecting hoisting and reduction works on the claim, and that 100,000 out of the 500,000 shares have been placed on the market for the purpose of raising the necessary money to provide these works. It looks very much as though Pike City is going to be one of the best gold districts in this, California's greatest mining county.

**MONTHLY CLEANUPS.**—The Young America cleaned up for the last month's run between \$22,000 and \$23,000. The Cleveland mine yielded \$2500 for the month.

## Siskiyou.

**SCOTT BAR.**—Yreka *Union*, July 8: The quartz excitement has somewhat subsided, although the mines all pay good wages.

**KLAMATH RIVER MINES.**—The Centennial Company is working full time and is taking out big pay. The John Knapper claim is being profitably worked by a Chinese company. The Fort Jones Company started its derricks last Saturday, and will run night and day until the season closes. Hoisting commenced in the Phil Mott claim Monday, and the owners are counting on a profitable run. The Kana Company has been hoisting for several days, with favorable results.

## NEVADA.

## Washoe District.

**CON. CALIFORNIA AND VIRGINIA.**—Virginia *Enterprise*, July 10: Work going on actively ahead as usual, with the regular daily yield of about 400 tons per day. The mill assays have shown considerable improvements over those of the last two or three months, all of which was needed. The drift explorations on the 1400 and 1650 levels are making good progress, and the old south drift on the 1950 level is being reopened. The official report of the mine for the month of June says: The number of tons of ore worked was 11,983, and the assay value of the bullion produced, subject to discount on silver, was \$105,116.27 against 12,040 tons worked in May, yielding bullion of the assay value of \$141,161.27. Although about the same quantity of ore was worked in June as in May, the bullion product was \$3,045 less. This was on account of the low grade of the ore. The yield in bullion of the ore worked at the Morgan mill in June averaged \$10.27 per ton against an average battery assay of \$13.47 per ton, the balance of the precious metals passing off in the tailings. The yield in bullion of the ore worked at the Eureka mill averaged \$7.79 per ton against an average battery assay of \$11.25, the difference, or \$3.46 per ton, passing off in the tailings. The expense account for June has not yet been received at the local office from Virginia City. The expenses of the corporation in May, when 12,040 tons of ore were mined and milled, were about \$140,000; therefore June, with 11,983 tons of ore mined and milled, they could not have been much less. If the \$105-

146.27 in bullion produced in June were sold, with silver at its present rates of discount, it would net the company \$91,451.16 in gold coin, and if the expenses in June have been as large as those of May, when about the same number of tons of ore were worked, there would be a loss to the company of \$48,549 for mining and milling ores in June.

**BEST AND BELCHER.**—Preparations are now being made to put in a substantial stone bulkhead on the 2319 or bottom level to shut off the heavy flow of water which comes in from the north country—very little comes in from the south. This north drift was commenced with the intention of being carried through to connect with the 2500 level of the C. and C. shaft, but was suspended at 300 feet. When this bulkhead is completed the sump will be pumped and cleaned out, and deeper sinking inaugurated. This sump or continuation of the shaft is 60 feet deep below the lower level.

**CHOLLAR.**—No advancement westward has been made in the new station on the 3200 level, owing to the opening out and starting of the lateral drift north to connect with the drift south from the bottom of the Hale and Norcross deep winze. This drift is now out 28 feet and being pushed ahead for all it is worth, commencing on the east side of the new ore vein and following along the east side.

**HALE AND NORCROSS.**—On the 3200 level the new lateral drift north from the bottom of the deep winze is advanced 32 feet toward the Savage line, making a total of 58 feet. Material in the face, vein porphyry, clay and quartz, giving low assays. On the 2900 level the west crosscut from the main north lateral drift is still following up the diamond drill hole, and showing well in good streaks and bunches of ore.

**SAVAGE.**—The principal work during the week has been confined to getting in the drain boxes throughout the main south lateral drift on the 600 level, and the requisite retimbering and similar work found necessary by the badly swelling ground passed through by the drift. The face of the east crosscut is still in favorable vein material.

**YELLOW JACKET.**—The old stopes and breasts from the 1500 level up continue their regular aggregate yield of about 140 tons per day, keeping the Brunswick mill steadily supplied. Further exploration work goes steadily ahead, opening up more ore resources to keep up the supply.

**SIERRA NEVADA.**—On the 520 level the north lateral drift from the west crosscut has gained 27 feet; total length, 251 feet. Material in face, vein porphyry, clay and a small proportion of poor quartz. A few tons of good gold ore per week are being taken from the croppings on Cedar Hill.

**GOULD AND CURRY.**—The west crosscut 50 feet above the 500 level has been extended 20 feet, making a total of 120 feet. The whole face is in mineralized quartz giving low assays. The north lateral drift has been extended 12 feet; total, 49 feet. No change in material.

**POTOSI.**—Nothing done beyond reaming out the long diamond drill hole, east on the 3100 level, preparatory to shoving the drill further east, to prospect and ascertain the dimensions of the great quartz vein demonstrated to exist at that point.

**ALTA.**—On the 700 level the west drift or crosscut from the main north lateral drift is making good progress toward intersection with the Keystone ledge, having nearly 100 feet further to go in order to reach it.

**CROWN POINT AND BELCHER.**—Full work going ahead at the regular old rate of 400 tons per day, as before the breakdown. The broken crank of the single hoist or north engine is repaired and all right.

**KENTUCK.**—About 40 tons per day is the regular yield of ore from the old workings above the 1300 level. This ore is all low-grade and being reduced at the Rock Point mill.

## Bernice District.

**BETTER PRICE WANTED.**—Silver *State*, July 7: In Bernice, Bothwell's mill is closed down. Messrs. Williams & Hoyt, the principal mining operators there, have refused to produce any more ore until a better price is paid for silver.

## Cottonwood District.

**QUIET.**—Silver *State*, July 7: For a combination of reasons, quietness reigns at Cottonwood, but good times are expected there before a great while. The Bell nickel and cobalt mine has been sold to an English syndicate, representatives of which are expected to arrive on the ground shortly. The ledge is six feet wide and of high grade. Before active work is resumed pumping machinery must be erected in order to rid the mine of water. Senator George Hearst and W. S. Keyes have bonded the Lovelock nickel and cobalt mine to an English syndicate. The ore of this property carries a higher per cent of cobalt but less of nickel than the Bell. Three thousand five hundred dollars have been paid on the bargain, and a cash sale, it is believed, will be effected in a few days. To the southwest of Cottonwood, some 30 miles, John T. Calvert has made a valuable discovery of a three-foot ledge of silver ore, assaying \$600 per ton.

## Eureka District.

**ORE SHIPMENTS.**—Eureka *Sentinel*, July 10: During the past week ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Richmond Works—Alexandria mine 1 1/2 tons; Phoenix, 17; Putnam, 8; Rothschild, 2 1/2; Delaware, 10; Eureka Star, 2; Red Jacket, 1; Hoosac, 43; Lone Pine, 1; Bullwhacker, 1; Geddes & Bertrand, 6; Jones, 1; Mt. Hope, 13. To the Eureka Con. Works—Cottontail mine, 1 1/2 tons; Reveille, 4; Morey, 6 1/2; Diamond, 3; Dunderberg, 31 1/2; Irish Ambassador, 11; Pioneer, 1 1/2; Jackson, 20; Alexandria, 6 1/2.

## Granite District.

**SUCCESSFUL.**—White Pine *News*, July 10: Ex-Senator Doolin and Thomas Kenny are meeting with deserved success in Granite district. They have now been working over a year on a lease on Fred Gotchett's gold mines. We learn they have exposed a fine body of ore and are likely to make a little fortune between now and the time snow flies.

## I X L District.

**TUNNEL.**—Silver *State*, July 7: In I X L district, Messrs. Sanford, Allen & Co. own on the west side of the district a mine into which they are run-

ning a tunnel 80 feet long to crosscut their ledge at a depth of 75 feet. At the bottom of an incline sunk into the ledge the ore assayed over \$200 a ton. These gentlemen own a two-stamp mill, but the ore is rebellious, and must, if worked properly, be roasted. Should the ledge hold out in extent and richness, roasters will be erected close to the mine before long. On the east side of the district C. S. Kellogg has two men employed in the Black Prince mine, running a tunnel to crosscut the ledge. They have 15 feet further to go. An incline sunk into the ledge is in ore that will work about \$40 a ton. Some of the assays run up to \$150. The Bay State Company is not doing anything at present.

#### Mount Rose District.

PARADISE VALLEY.—*Silver State*, July 13: Ore produced by Paradise mine for week ending July 7: Milling ore, 168,500 lbs; first-class ore, 6000 lbs. Ore delivered to the mill, 174 tons, 500 lbs. Number of tons of ore milled, 140. Average assay value, per ton, 69.95 oz. silver; 0.49 oz. gold. Bullion produced, from 31,859 lbs. concentrations, \$70,708.12 par value. Shipped to Boston & Colorado S. Co., 358 sacks of ore, valued at \$10,708.12. Mill work—Three Huntington centrifugal roller mills and six Triumph concentrators. Number of men on pay-roll, 121, of whom 46 are miners; on dead work, 25; ore extraction, 21; ore sorters, sack sewers and rock breakers, 12.

#### Park Canyon District.

GOOD WORK.—Belmont *Courier*, July 8: The furnaces in the Giant mill, Park canyon, Nye county, are now doing good work, and the ore is chlorinized up to between 85 and 90 per cent of its assay value. Superintendent John Truman is confident that there will be no more trouble with the furnaces. There is enough ore in sight in the mine to keep the mill running for years. There are about 30 men on the pay roll.

#### Reveille District.

GILA MINE.—Belmont *Courier*, July 8: The mine is looking well and shows ore in good paying quantities ready to stope. In the new find in the mine, a winze has been sunk 75 feet in good ore all the way. This winze is now connected with the main workings of the mine by a tunnel. The ore is of a good grade, assaying as high as \$900 per ton. Foreman W. Norris informed Ed. Cavanaugh that the mine was in a condition to work several more men, and that after the arrival of Governor Jewett W. Adams, about July 15, the force would be largely increased. Reveille will be a live camp this summer and fall.

#### San Jacinto District.

TRYING THE LEACHING PROCESS.—*Silver State*, July 8: Martin and Andrewartha, two practical miners and ore dressers, left here yesterday for San Jacinto district, west of Rye Patch, where they contemplate starting leaching works for the reduction of the ores of that district. If they cannot succeed in leaching the ores they will reduce them for shipment by the Cornish jigger process.

#### Tuscarora District.

NORTH BELLE ISLE.—*Times-Review*, July 9: The crosscut near the old shaft, 150-foot level, has been extended 18 feet.

NAVAJO.—South drift on the west vein, 150-foot level, has been extended 12 feet. No. 7 upraise on the east vein, same level, has been carried up seven feet. The stopes on this level have yielded the usual amount and grade of ore. During the week the station at the shaft, 150-foot level, has been retimbered. Mill running as usual.

#### Ward District.

BULLION SHIPMENTS.—White Pine *News*, July 10: The Martin White Mining Company at Ward shipped this week through Wells, Fargo & Co.'s Express, bullion valued at \$5900. The Monitor Mining Company shipped this week through Wells, Fargo & Co.'s Express, bullion valued at \$7000.

#### White Pine District.

THE SWEETWATER.—Eureka *Sentinel*, July 8: All the workings in connection with the Sweetwater Mining Co. at Hamilton are reported to be running along smoothly. Some two weeks ago a bullion shipment was made by the company, and yesterday a bar valued at \$972.20 was shipped by them through Wells, Fargo & Co.'s express here. The principal mine, the Stafford, is looking well and is keeping up its regular output of ore. The company employ, all told, some 60 or 70 men in and about the mill and mine, including the Wheeler tunnel, which is looking quite flattering. It is said that a big development may be expected in that quarter ere long, the face showing up ore that will go as high as \$2000 per ton. The tunnel is now getting under the "Original Hidden Treasure," and a month's more work will determine whether the company is to have an old-time bonanza or not.

#### ARIZONA.

RICH ORE.—Prescott *Courier*, July 10: George H. Wickler tells us that his Challenge mine is yielding rich ore in abundance. It is in Hassayampa district, about 14 miles from Prescott. Carloads of the ore will soon be shipped to some Colorado smelter. Mr. Turner, of Upper Big Bug, is in Prescott and tells of rich strikes in the Morning Glory and Middleton mines. The last-named mine is in Big Bug district, the former in Turkey creek. Rock from both ledges shows a great deal of free gold. Five men keep the Morning Glory mine supplied with all the rock it can crush. A gentleman from Bradshaw says there are in the district some 12 mines from which rich ore is being mined. The Lynx Creek mill is making a very successful run, and the Del Pasco is grinding out plenty of gold. John Lawler is making new strikes in Eureka district, near the big copper mines.

MOHAVE COUNTY.—*Miner*, July 10: Messrs. Ayres and Kennedy have struck a large body of galena ore on the old Union mine, and have a carload on the dump, besides about 40 tons stripped ready to take down. The ore is said to average about 35 ounces in silver and 1½ ounces in gold to the ton and about 50 per cent lead. Mr. Ayres thinks he has a fortune in sight and we hope it may prove to be so. On the Prosperity mine Messrs. Layne and Sullivan are taking out some \$300 ore from a winze

in the south drift. James Smith has taken a contract to sink an air shaft on the Golconda mine near Todd Basin. Win. Sherman and Johnny Granfield are working on the old Morgan mine at Cerbat and will soon have a carload of galena ready to ship. Jim Mulligan has three or four tons of high-grade ore on the dump of the Flagstaff mine, the result of his labor for a few weeks past. Messrs. McLean and Roberts are pegging away at their tunnel on the Mariposa mine, and are in about 75 feet in three weeks' work. The rock is getting harder and some water is already coming in.

GLOBE.—*Silver Belt*, July 10: Salter & Co. will start the Centennial mill next week on 30 tons of ore from the Centralia mine. Frank Burke, W. A. Holmes and Jim Lewis will send them 10 or 12 tons for reduction. Work was resumed at the Old Dominion Company's mine and smelter on Tuesday.

RICH.—Garlinghouse is taking ore out of the old Democrat mine at McMillen that is said to go as high as \$10 per pound.

#### COLORADO.

GOLD.—*Tribune-Republican*, July 10: The production of gold is receiving more attention in Colorado this year than usual. There is scarcely a gulch or bar in the State, which gives promise of pay, that is not being worked. Regions that have not, in past years, added many golden grains to the total product, will yield their quota this season, providing they contain it to yield. The Hahn's Peak placers are bidding fair to turn out \$100,000 this year, which is nearly double their past product. San Miguel, which has been dead and quiet for years, will see dirt flying before fall. In Park county, about Hamilton, giants are cutting away banks where only the pick and shovel have worked before, and on the Sovereign mine there is fair promise of a large yield from newly-discovered ground. The news from Junction City, La Plata county, is favorable and the gold-bearing gravel is said to be rich and yielding well. The latest discovery in the placer line is reported to be in Conundrum Gulch, in Pitkin county. The *Herald-Democrat* gives the following account of it: Last season a number of placer claims were located in Conundrum Gulch. Upon some of these claims work was done then. Late in the season Mr. Wm. Harris found the Kansas claim in a small gulch running up from the east side of Conundrum proper a short distance above Red Hill and near the properties of Messrs. Webber, Lee and others, but owing to the lateness of the season and the near approach of snows concluded not to locate the property until this year. On the 19th inst. he located it. Mr. Frank Burno, deputy sheriff, is associated with him. On Saturday and yesterday some dirt from the surface was panned with most encouraging results. One pan (a common wash basin being used) yielded \$1.50 in value. The gold is of a superior quality. From the washing of a few pans of dirt Mr. Burno has a vial partly filled with nuggets, one of which is worth more than \$1. The owners of the Kansas claim will put in a flume at once and begin work to extract the precious metal that only awaits their taking. A stream of water runs through the claim sufficient for washing. The news of this rich find spread through the town on Saturday evening, and yesterday a number of prospectors turned their heads Conundrumward to try their luck. This new find will stimulate work on the other properties in Conundrum Gulch.

FREELAND.—Idaho Springs *News*, July 9: Work at the Freeland goes on as regular as the rising and setting of the sun, under the foremanship of old Jack Prout. The usual large reserves of ore are kept open for a year or two's supply, and from 70 to 80 tons are sent daily to the concentrator, which, in turn, is hauled to the railway switch at the mouth of Trail creek, where it is sampled and purchased by Mathews & Webb, ore and bullion brokers. Sinking has been resumed in the Freeland.

#### MONTANA.

THE GRANITE MOUNTAIN.—*Inter-Mountain*, July 8: In St. Louis yesterday the Granite Mountain Mining Company paid a dividend of \$100,000, being 25 cents per share, and making \$620,000 of profits divided this year to date. The Granite Mountain is not only the most valuable silver property in Montana, but it is the richest on the continent, and is paying heavier dividends than any other. When it is considered that the company is maintaining its present vast output with but a 30-stamp mill in operation, the record must be regarded as a marvelous one. But the end is not yet. The erection of a new mill containing 40 stamps is in contemplation, and while the new enterprise will not double the output, because some ore of a lower grade will be worked, the bullion product will yet be materially increased, and the profits divided will, of course, be correspondingly larger. That we are safe in making these promises is evidenced by the fact that recent reliable reports of the ore in sight in the Granite Mountain estimate its value to be not less than \$20,000,000—a claim that can be urged on behalf of but few mines in the known world.

#### OREGON.

QUARTZ AND PLACER.—Jacksonville *Times*, July 9: A cleanup is being made at the Sterling mine, which will be completed in about a month. Baume, Klippel & Co. are figuring on a new quartz mill, which will in all probability be put up soon. Wimer & Sons are cleaning up at their mines near Waldo, and we expect to hear a good report from there. Considerable prospecting is going on in Josephine county and several good placer mines will be opened there in the near future. J. C. Ruck is still engaged in rocking at his diggings in Willow Springs precinct. He has abandoned his quartz mines for the present. Chris. Kretzer, who has a good mine on Shiveley gulch, recently found a nugget, containing gold and silver, worth about \$60. John Haviland, who has a hydraulic claim near Kerbyville, is crushing the cement, which is abundant there, with good results. He has done well during the past season. The California company which proposes running a ditch from Sucker creek to the Illinois river, with the intention of working some rich mines, commenced operations a short time ago. B. A. Knott, of Willow Springs precinct, has about 200 tons of ore from his mine on the dump near L. D. Brown's mill, which is now being crushed. It is much harder than that

obtained from Swinden's ledge, but is said to prospect fully as well. L. D. Brown is now in Portland for the purpose of purchasing a five-stamp mill, which will be put alongside the one at present working at the Swinden ledge in Rock Point precinct. The ore is so rich and easily obtained that the full capacity of both mills can be taxed. A company, composed of Wm. Naucke, Wm. Bybee, John Hall and A. Brown, has inaugurated a new enterprise and will engage in mining on Canyon creek on a large scale. A ditch will be dug, hydraulic pipe and a giant purchased and nothing left undone to make its diggings pay. C. C. Beekman is having his quartz mines on Jackson creek surveyed, and will probably have tunnels run and shafts sunk on them before long. We believe that good ore exists there in paying quantities, and hope to see the matter thoroughly tested soon. B. B. Beekman and Frank Huffer are engaged in making the survey.

#### NEW MEXICO.

BULLION.—*Silver City Enterprise*, July 9: The bullion shipments for the month of June from this point by the Wells, Fargo & Co. express amount to \$50,901.30. Of this amount \$25,000 was in gold dust and gold bricks, which came in from several different gold camps. One thousand dollars was in bullion shipped by Meredith & Ailman, who purchased it in small quantities from various producers. Fifteen thousand sixty-eight dollars and fifty-five cents was shipped by Thos. B. Pheby, of Georgetown, and the balance, \$9832.85, by Payne, Washington & Co., of Georgetown. J. K. Wagner, of Wells, Fargo & Co.'s express, states that the past month was one unusually light for Georgetown, which, as a general thing, ships about \$40,000. Seven silver bricks, worth about \$1000 each, were shipped on Saturday by Payne, Washington & Co., of Georgetown, through the express office of this place. The bricks were the production of the McGregor mine, which is now owned by the Parapet Mining Co. Owing to the dry spell the company has been compelled to close down the mill for the present, but will continue developing the mines and taking out ore, which will be stowed away until there is a sufficient flow of water to start the mill. The company recently purchased the hoister formerly in use at the Ivanhoe mine, which will soon be put in place on the McGregor. The sale of the Atlantic mine at Pinos Altos is now understood to be off. It was to have been consummated upon the first of the present month, but because of a failure to arrive at an understanding that would be mutually satisfactory nothing was done, nor does it now appear likely that there will be. All of the conflicting interests of the owners of the Peerless mine have been compromised and a corporation formed. J. Will Boyle, vice-president of the Merchants' Exchange bank of St. Louis, is largely interested in the property. As soon as several little matters are adjusted work upon the property will be resumed with a result that cannot fail to be satisfactory to the company.

#### UTAH.

MILFORD.—Cor. Salt Lake *Tribune*, July 7: The Star Concentrating mill has run steadily all the past week under the able management of John Kerby. Wall's patent rolls have proved a success, and about 30 tons of hard ores are put through every ten hours. The mill is to be run night and day after the glorious Fourth. The mill is a success and if the ore bodies hold out, which they now bid fair to do, Star Precinct will take the lead of mineral producers in Southern Utah. Outside of the concentrations (which average 60 per cent lead, 35 ounces silver and from \$6 to \$20 gold per ton) extensive shipments of first-class, or ores going over 35 per cent lead, have been sent to the smelters north. The sampling mill is kept busy most of the time sampling ores for different parties. Among the mines now shipping 1 note the Elephant, leased by Wm. T. Milton, which is now showing well. This mine is owned by the Davenport Mining Co., of Iowa. The Burning Moscow, Golden Era, Rebel Flora, Wild Bill, Monitor, Florence Adelia, Hickory, Hidden Treasure, Congo, Blue Cloud and a number of others are also shipping.

REVIEW.—Salt Lake *Tribune*, July 9: The week has seen no important transaction in mining circles. The weather has been dry and sultry, and the output of ores free. The June report of the Ontario product showed 68 bars of bullion, 39,676.35 fine ounces, and nine lots of ore sold for \$77,463.67; an aggregate value, approximately, of \$117,140.02, making the product of the Ontario for the six months of this year, \$886,718.42. Out of this six regular monthly dividends of \$75,000 each have been paid, a total of \$450,000. The product of the Daly for June was \$56,062.66 of fine bullion, and four lots of ore sold, aggregating \$82,819.53. For the five previous months the Daly product was \$228,851.52; thus the six months' product was \$311,729.05. The shipment of ores out from this city for the week ending Saturday, July 3d, inclusive, was as follows: 36 cars bullion 869,832 pounds; 14 cars ore, 403,400 pounds; 5 cars copper ore, 143,400 pounds; total 55 cars 1,416,632 pounds. The shipment of ores abroad was light compared with the total receipts, which for the week ending July 7th, inclusive, were value of \$110,349.63. For the same period the receipts of bullion were \$152,664.8. Aggregate value of receipts of bullion and ore, \$263,013.11. For the previous week the receipts were \$160,178.55, of which \$101,602.98 was bullion, and \$58,575.57 was ore. The Ontario output for the week could not be got; it is probably about the difference between the "fine bars" and the Daly product. The Daly product for the week was six bars of bullion, \$7982.25; ore sales, \$8692.71; total, \$16,674.96. All goes well with this fine property. Base bullion receipts for the week were valued at \$19,200; fine bars, \$44,600. The Hanauer smelter product for the week was \$29,895; the Germania, nine cars, \$19,205.62; the Pascoe, \$3105. The Stormont sent up two lots of silver during the week, \$4555. Five hundred shares of this stock sold in New York on the 2d at 12 cents. Ore receipts for the week were \$27,145 by Wells, Fargo & Co.; \$45,075 (including \$2700 from the Queen of the Hills and \$1260 from the Overland), by McCormick & Co.; and \$38,129.63 by T. R. Jones & Co. Nothing new from the Horn Silver; no way of working its base, low-grade ores is yet found, the experiment recently at Campbell's concentrator having proved a failure.

#### List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in DEWEY & Co.'s Patent Office Library, 252 Market St., S. F.

FOR WEEK ENDING JULY 6, 1886.

344,892.—ROCK DRILL—C. O. Barlow, S. F.  
344,896.—TRIGGER ATTACHMENT FOR DOUBLE GUNS—C. E. Burgans, Oakland, Cal.  
344,950.—DISK SEEDER—B. C. Dorsey, Porterville, Cal.  
344,830.—GANG FLOW—P. Hansen, Fresno, Cal.  
344,915.—BLOW GUN—Lang & Hart, Stockton, Cal.  
344,916.—GAS CUT-OFF—Chas. Leech, Oakland, Cal.  
345,075.—FENCE POST—J. L. Quackenbush, Portland, Oregon.  
345,177.—MIDDINGS PURIFIER—R. A. Rew, Pomerooy, W. T.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

#### Mining Share Market.

The mining share market is not by any means so active as to keep all the brokers busy. In the middle Comstock mines there is little forward movement, although the situation is represented as good, with a prospect for development of good ore in Savage, Chollar and Norcross.

The following statement shows how the companies stood financially on July 1st—the amounts named being cash on hand: Alta, \$20,452.26; Alpha, \$13,891.97; Best and Belcher, \$4637.08; Benton, \$783.53; Chollar, \$36,576.97; Consolidated California and Virginia, \$23,951.76; Exchequer, \$3098.27; Gould and Curry, \$362.29; Hale and Norcross, \$16,631.79; Mexican, \$3735.75; Occidental, \$1648.27; Ophir, \$1229.76; Sierra Nevada, \$12,151.87; Utah, \$5273.94.

#### Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Mt. Diablo (for June), \$40,440; Ontario (for June), \$117,140; Consolidated California and Virginia (for June), \$105,116; Daly (for June), \$56,062; Mt. Diablo, July 6, \$5076; Lexington, July 8, \$25,900; Moulton, 8, \$16,800; Dexter, 8, \$3072; Alice, 6, \$47,776; Marget Ann, 9, \$3416; Hanauer, 7, \$18,200; Pascoe, 7, \$1600; Stormont, 7, \$2325; Overland, 8, \$1260; Germania, 8, \$6363; Germania, 9, \$6488; Alice, 9, \$12,447; Queen of the Hills, 9, \$1135; Germania, 10, \$4336; Hanauer, 11, \$6130; Crescent, 11, \$9,530; Germania, 11, \$2137; Queen of the Hills, 11, \$1350. Shipments from Salt Lake City, for week ending July 20, were 33 cars of bullion, 799,506 pounds; 12 cars ore, 380,800 pounds; one car copper ore, 23,100 pounds; one car sulphur, 27,000 pounds.

#### New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

KIRBY MILLING AND M. CO., July 10. Capital stock, \$1,000,000. Directors, Martin Erickson, A. W. Huggins, John O. Wilkins, William Coker, J. J. Aiken.

CHICAGO M. & M. CO., July 10. Capital stock, \$2,000,000. Directors, P. A. Doane, C. H. Eaton, J. M. Bryan, R. C. Cheeseborough and G. W. Watson.

SOUTHERN PACIFIC MILLING CO., July 14. Object, buying and selling wheat and making flour in San Luis Obispo and Monterey counties. Capital stock, \$200,000, in \$100 shares. Directors, M. C. Ellis, R. M. Shackelford, F. L. Parker, P. Fellows and C. O. Alexander.

AUTOMATIC CARBURETING GAS AND LAMP CO. Object, to make and sell automatic lamps and deal in patent rights. Capital stock, \$100,000. Directors, J. G. Colmesnil, J. H. O'Dell, R. T. Shannon, W. H. Shannon, H. C. Willis and E. Jesuran.

#### Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

#### Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

**Chicago Prices Beaten!**  
ESTABLISHED 1860.  
**S. F. PIONEER SCREEN WORKS,**  
221 & 223 First St., cor. Tehama, S. F.

Sheet Metals of all kinds perforated for Flour and Rice Mills, Grain and Malt Driers, Furnaces, Churns, Cement and Smut Mills, Separators, Revolving and Shot Screens, Stamp Batteries and all kinds of Mining and Milling Machinery. Inventor and manufacturer of the celebrated Slot Cut and Slot Punched Screens. Mining Screens a Specialty, from 1 to 15 (fine).  
Orders Promptly Executed

### IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the **IMPROVED FORM OF HYDRAULIC GIANTS**, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. R. Hoskin et als.

Prices furnished upon application to

**JOSHUA HENDY MACHINE WORKS,**  
39 to 51 Fremont St., San Francisco, Cal.

This cut represents our  
**IMPROVED HYDRAULIC MACHINE.**  
IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List.  
**HOSKIN & CO., Marysville, Cal.**

### THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the **Jenkins Standard Packing** can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

Manufactured only by

For Sale by **DUNHAM, CARRIGAN & CO.,** San Francisco, Cal. | **JENKINS BROS.** 71 John St., New York.

114-118 Pine Street, - San Francisco.

We would call the attention of Assayers, Chemists,  
Mining Companies, Milling Companies, Prospectors, etc.,  
to our full stock of Balances, Furnaces, Muffles, Crucibles,  
Scorifiers, etc., including, also, a full stock of  
Chemicals.

Having been engaged in furnishing these supplies since  
the first discovery of mines on the Pacific Coast, we feel  
confident from our experience we can well suit the de-  
mand for these goods, both as to quality and price. Our  
New Illustrated Catalogue, with prices, will be sent on  
application.

Our Gold and Silver Tables, showing the value per  
ounce Troy at different degrees of fineness, and valuable  
tables for computation of assays in grains and grammes,  
will be sent free upon application. Agents for the Patent  
Plumbago Crucible Co., London, England. Also for E.  
G. DENNISTON'S Silver Plated Amalgam Plates. The  
plates of this well-known manufacturer are thoroughly  
reliable, and full weight of Silver guaranteed. Orders  
taken at his lowest prices.

JOHN TAYLOR & CO.

Send for Catalogue! AND MADE IN STYLES AND SIZES TO SUIT.

THE FOODS MANUFACTURING CO., - - Springfield, Ohio

ADAMANTINE.

We manufacture the above Adamantine  
Shoes, Dies and Crusher Plates. They are in  
use on the hardest quartz in the United States  
and South and Central America, and have been  
for the last ten years; we warrant them to out-  
wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times  
longer than any other make. They never break AT THE SHANK, and the wear is so light  
that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.

For further particulars, address

**CHROME STEEL WORKS,**

H. D. MORRIS, Agent, 22 Fremont St., San Francisco.

When ordering, a rough sketch, with full dimensions, is all that is necessary.

## CHILLED CAR WHEELS.

**THE NEW COSO MINE.**—A suit has been commenced by the New Coso Mining Company against Thomas Bell, L. L. Robinson and the executors of the will of Alexander Forbes to recover \$72,791.12, with interest. The defendants were directors of the plaintiff corporation, and it is alleged that they mismanaged the affairs of the corporation in such a neglectful manner that no accounting was made for moneys received from sales of bullion, assessments, etc.

**THE new steel water-steamer Balboa,** just completed by the Union Iron Works for the Panama Railroad Company, had a trial trip this week. The contract called for a speed of nine knots, but a speed of 10½ was easily developed.

A GREAT deal of copper is being consumed at present; but the price remains stationary, while production is said to be falling off, except in the lake districts.

SEVERAL thousand pack animals are in constant use by Walla Walla traders in sending supplies to the numerous mining camps which can be reached in no other way.

THE big discount on silver is very detrimental to profitable mining for the white metal. Only ores of a high grade can be handled without loss.

MULLER'S success dates over a quarter century. Optical Depot of the Pacific Coast, 135 Montgomery St., near Bush.

Reduction of Ores, Quartz, Phosphate Rock, Carbon, or other Mineral Substance to any degree of fineness in a rapid and economical manner.

Any method of amalgamation may be applied.

At 300 revolutions per minute will pulverize 2000 pounds of quartz per hour to 60 mesh dry, and from 3000 to 6000 pounds wet.

All wearing parts easily and cheaply replaced. May be seen in operation at the New York Metallurgical Works, 104 and 106 Washington St., and Pacific Iron Works, San Francisco.

Certificates as to performance of the Mills, and any information required, furnished on application.

## THE FRISBEE-LUCOP MILL CO.,

Office, 104 & 106 Washington St., NEW YORK.  
OR PACIFIC IRON WORKS, SAN FRANCISCO.

## CALIFORNIA ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE  
DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

OFFICE, 404 MONTGOMERY STREET, SAN FRANCISCO.

EGBERT JUDSON, President.

ALBERT H. REICHLING, Secretary.

G. GOODMAN, Manager

1850.

...BUILDERS OF...  
**MINING MACHINERY.**

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING and REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

### WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

### Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

## HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

# \$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,  
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.**  
(\$575 00), F. O. B.

**OVER 1,000 ARE NOW IN USE.** Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

SAN FRANCISCO, CAL.

# \$1,000 CHALLENGE ACCEPTED, PRICE, FIVE HUNDRED AND FIFTY DOLLARS (\$550.00).

**THE  
"TRIUMPH" ORE CONCENTRATOR.**

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE, placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

**DAMAGED BY FIRE!****Engines, Boilers, Wood and Iron Working Machinery, Belting, Etc.****FOR SALE CHEAP!**

The fire which destroyed our building, Nos. 25 to 31 Main Street, on the 20th of June, will have no effect on our business.

We have already secured one of the stores in the magnificent Donahue Block, Nos. 34 and 36 Fremont Street, near Market, the finest in the city.

We have removed our Machine Shop to Nos. 225 and 227 Beale Street, and are now in full blast.

Our Oil Warehouse is located at 519 Front Street.

Our Oregon Branch is still at 91 and 93 Front Street, Portland.

Constant arrivals of new stock will enable us to supply our customers with everything of the latest and best description.

In addition, we shall have all of our old stock of Machinery, much of which had just come in, removed from the burnt building to our new store, where we shall be able to offer it at **EXTREMELY LOW PRICES.**

When the fire occurred, we had, fortunately, finished shipping the mammoth mills for La Trinidad and Silver Queen Mines, of Mexico, and the 20-Stamp Mill for the Buchanan Mine, of Tuolumne.

Notwithstanding our fire, the Pacific Lumber Company, of Humboldt, awarded us the contract for their new mill over all competitors, preferring to wait till our New Shop was ready rather than get their Machinery elsewhere, though they are in a great hurry. We consider their action conclusive evidence of the superiority of our Machinery, as they are determined to have the finest mill on the Coast.

Our New Concentric Set Works and Headblocks, and the Sinker, Davis &amp; Co. Band Log Mill, which we recently furnished the Humboldt Lumber Company, of Humboldt, are pronounced by them superior to any ever seen in Humboldt.

We are now at work on nine Headblocks for Pope &amp; Talbot Mills on the Sound.

From the above facts, it would appear that we stand fire pretty well, and if our patrons will kindly continue to favor us with their valuable business, we will do our best to excel our former efforts.

**TATUM & BOWEN, San Francisco and Portland.****IMPORTANT TO GOLD MINERS!  
SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD**

IN QUARTZ, GRAVEL AND PLACER MINING.

**Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.****BEST SOFT LAKE SUPERIOR COPPER USED.**

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

**SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.****E. G. DENNISTON, Proprietor.**

These Plates can also be procured of JOHN TAYLOR &amp; CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

## The Tustin Ore Mill.

This mill has been on the market some little time, but only recently attracted much attention from the results it accomplished in the several practical trials at the Oro Plata mine, Murphy's, Calaveras county, where, on the ore there worked, it is stated to have excelled the stamps. It did this by producing a pulp very free from slime, and in a most favorable state for either amalgamation or concentration. The slimes made by this mill do not average more than from one-fourth to one-eighth of that made by stamps, and it is claimed that from 20 to 40 per cent more gold and sulphurets were saved. The mill has gone through the experimental stage and is now much improved. To run the largest machine less than four and a half horse power is required. The weight of the large mill is 13,000 pounds, and the heaviest piece weighs 1270 pounds.

By reference to the three engravings a clear idea of the machines can be obtained.

Fig. 1 is a general view, a portion of the external case being cut away to show the screens, slotted grate and dies, hand-hole plates and driving gear. Fig. 2 is a sectional view through the center. The principal parts shown are the two loose rollers (10-10), slotted grate dies (11), screens (14), yoke bar (15). The machine revolves in the direction shown by the arrow, and when in operation the rollers keep the position shown. Fig. 3 is a sectional view through the center, at right angles to that of Fig. 2.

The barrel turns upon two hollow trunnions

tween and under them. The crushed ore drops through the slotted grate dies (11) and on the screens (14). The screening takes place in the lower right hand side (Fig. 2), nearly all of the pulp being discharged under the two rollers.

screen but once. For this reason a high per cent of the ore grains are nearly of the same size as the screen, and very little slime is made. When the machine has the proper feed the rollers are nearly stationary, as shown in Fig.

into the feed hopper of the machine, and in this way a very perfect automatic feed can be had.

Two liner rings (9—Figs. 2 and 3) are secured to the heads (7 and 8) and serve to take up the wear from the ends of the rollers, and prevent damage to the heads. The hand hole plates (13) serve to remove bits of steel or iron that may accidentally enter the machine. For wet crushing, water is admitted on the screens by the nozzle (38). The following statement of results, made by Luther Wagoner, M. E., gives some interesting figures: Lot 1—Twenty-eight tons of ore furnished by C. W. Tozer, superintendent Angels' quartz mine. Lot 2—Twenty-five tons of ore furnished by Judge Hewel, superintendent of the Utica mine. Both lots of ore were composed of talcose slate and some quartz, slate and talc being the prominent feature. They were worked at Murphy's, Calaveras Co., using one Tustin pulverizer and three Frue vanners. Screen, 20-mesh steel-wire cloth.

### MILLING RESULTS.

	Lot 1. Tozer.	Lot 2. Hewel.
Number of tons of ore milled...	28	25
Time, in hours, to mill the ore...	40	27
Power used to run the Tustin pulverizer.....	4½ H. P.	4½ H. P.
Bullion amalgamated on plates, per ton.....	\$1.46	\$2.07
Bullion amalgamated and left on plates, estimated.....	.35	.12
Sulphurets saved. Value, per ton, of ore.....	4.25	1.52
Sulphurets left in boxes and otherwise lost, estimated.....	.27	.07
Assay value of tailings. Mean of 8 assays.....	.83	.90
Value of the ore per ton.....	7.16	4.68
Assay value of sulphurets per ton, gold.....	126.83	68.90

From the above results and personal knowledge of the ores of the camp, I believe it safe to say that the use of the Tustin mill and Frue vanners will enable the ores to be worked so as not to leave more than 75 to 90 cents in the tailings, and that from 17 to 25 tons of ore per 24 hours is a fair estimate of the capacity of the

Fig. 1.—GENERAL VIEW OF TUSTIN ORE MILL.

Fig. 3.—SECTIONAL VIEW AT RIGHT ANGLES TO Fig. 2.

Fig. 2.—SECTIONAL VIEW THROUGH CENTER.

(7-8, Fig. 3). Ore is fed into the hopper (31) and by the feed tube (33) is delivered inside the barrel; this feed is regulated by a hand wheel (29) that alters the throw of the hopper by means of the cam (25) on the hand-wheel shaft. The throw is made by the ratchet wheel (23) on the hollow trunnion (8), in combination with a spring shown in Fig. 1. The ore falls on and under the rollers (10-10), and is crushed be-

As the screen revolves, the coarse pulp falls down the screen and rolls into the large opening in the grate die near (11, Fig. 2). When this opening is nearly overhead the coarse ore falls back under the rollers to be recrushed.

Owing to the free escape of the crushed ore through the slotted dies, and the ample screen surface, it is almost impossible for the rollers to run over a grain small enough to pass the

2, but if the feed is scant, then they oscillate right and left like a pendulum. In doing so they strike the shoes (16) of the indicator yoke (15) and cause the pointer (22) to oscillate. This shows the attendant what is going on in the inside of the machine, and also shows that more feed is needed. By attaching a cam to the indicator shaft, this motion can be used to operate any self-feeder, the latter discharging

machine. Mr. F. B. Morse, the superintendent, examined the assays and statement of results above given, and states that they are correct.

The machine is adapted for both wet and dry crushing. It is made in this city by Hinckley, Spiers & Hayes, Fulton Iron Works, who have spared no trouble in perfecting its details so as to make a good practical ore pulverizer.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

## Common-sense Geology—No. 3.

[Written for the Press by JUSTIN CHENOWETH.]

Opposite to this stretch of sandstone heretofore described and lying only a few miles to the westward is the northern extremity of a chain of islands having an aggregate length of fully 30 miles. Within that length there are only three separations by water, no one being of great width. Along the water line they are all composed of a dark-colored trappean rock, identical in appearance and composition, and may, therefore, in a geological sense, be regarded as a continuous body of land the entire distance of their aggregate length. At frequent intervals along the wave-beaten rocky shore of this chain of islands, there are visible outcroppings of petrified seams of coal; some of them having a thickness of fully 10 feet.

I speak of it as being petrified for the reason that from some cause it has been changed to a stony character so that it will not burn, though yet sufficiently soft to blacken the fingers when handled; and where exposed to the constant wearing action of waves, presents the same appearance as a freshly opened seam of free burning coal. The seams uniformly dip to the northward at an angle of 45 degrees, and, therefore, by geological rules, the inclosing rock will necessarily be regarded as of aqueous origin, stratified and inclined at the angle indicated by the coal seams. Under the same rules it cannot be regarded otherwise than as a single formation, having a thickness of about 22 miles. The preceding examples that I have given prove conclusively that in some instances, at least, inclined strata have been originally deposited in the position in which they now appear, and therefore disprove the assumed principle of universal original horizontal deposition. The two last do more. They show the absurdity of the principle on which superposition of strata is decided in so far as it relates to geological chronology.

It may be observed in the sandy bed of clear rivulet, or of any tidal slough in which the same kind of bottom is periodically laid bare, that in either case where there is any considerable current, the surface of the ground is always thrown into a regular succession of ridges nearly at right angles to the direction of the current. They uniformly rise with a gentle ascent, in the direction of the flow, to a certain point where the ascent terminates in a steep talus, at the foot of which another ascent begins, and is terminated in a similar manner; the process being repeated *ad infinitum* along the course of the stream. Small pieces of sticks, leaves, grass, etc., that have become water-soaked, so as not to float on the surface, will be driven along and accumulate at the bottom of each talus, and frequently extending nearly to the top. Where there is a sharp bend in the course of the stream the projecting point of land will produce a spot of still water below it; or an obstruction of some kind, such as a stone or sunken log, will have the same effect in midstream.

At these points the sandy bottom will have a level surface on which is likely to be resting a complete covering of the lighter materials heretofore described, if there be a considerable quantity of such substance present in the stream. In my opinion, this gives an illustration on a small scale of the manner in which the two stretches of rocks in Puget Sound were formed at a time when the whole surface of the earth was covered with water flowing with a strong current from the tropics toward either pole; and that in this manner the chief mass of sedimentary rocks now visible in all parts of the world, with the coal-beds which they contain, resulted from a cataclysm. One strong confirmation of such a conclusion consists in the fact that the islands of Puget Sound and the Gulf of Georgia, wherever they have a rocky surface exposed, on the southern side or end, it uniformly slopes gently to the southward, while the northern extremity as surely exhibits a bluff. The same peculiarity appears with the islands on the eastern side of the North American continent; and I apprehend that observations made in that connection in all parts of the world would reveal the same peculiarity prevailing everywhere, the only difference being that in the southern hemisphere the gently sloping surface would be toward the north. In a superficial view of the subject it might be considered that the various theories concerning the fluidity of the interior body of the earth had no relation to that feature of geology to which I am specially directing attention. I will show that they have a direct connection with it. Until quite recently geologists taught that the main body of the earth was at the present time a molten fluid mass, having a solid crust only about 30 miles in thickness; but astronomers by means of cold facts and figures have compelled them to admit that it is a solid body throughout, certainly possessing greater rigidity than a solid globe of glass of the same size would have. They seem to have disregarded the fact that if the principle on which they relied to prove fluidity was sufficient for their purpose, when pushed to extremities it proved entirely too much. There cannot be any physical cause assigned for an increase of heat in proportion to the depth until a sufficient degree has been attained to melt all known substances and then stop. If it

were to continue in the same ratio, at a comparatively inconsiderable distance from the surface, all known substances would become volatilized by heat, and the earth would be merely a huge balloon having a rigid shell proportional to the mass, only about one-third the thickness of that of the egg of the barnyard fowl. It will not avail to assume that the gases might be held in a viscid state by external pressure; for it is yet an essential part of the system, having no regard to its present condition in that respect, to assume that at the time the visible portion of the earth's surface was molded into its general contour with the inclinations and contortions which the different strata exhibit, the interior of the earth was in a molten condition, and that the crust during that period was repeatedly broken through. Reasoning by analogy, a fracture of the crust would admit the atmosphere, and if that did not cause an explosion it would certainly create an expansion so great as to destroy the crust already formed. Geologists have compared the cooling earth to a shriveling apple, and on such comparison have based all their theories relating to the formation of oceans and continents, with the mountains, the contortions, and inclination of strata pertaining to the latter. It is not a logical comparison. The skin of a fresh, plump apple presents a smooth surface incapable of condensation in the line of the circumference; consequently, when the interior body of the apple is lessened in size by evaporation the skin becomes wrinkled or contorted. Presuming the earth to have been a mass of molten matter cooling into solidity, the conditions would be entirely different. If the Newtonian theory of gravitation be true, the most dense portions of the earth would then sink, so to speak, toward the center of the mass; consequently, as the surface became condensed by cooling, it would immediately gravitate toward the center, and that process would be continued until a solid nucleus would be formed and congelation proceed from the interior toward the surface instead of from the surface toward the interior, as the present system of geology requires. The manufacture of shot affords an illustration on a small scale corroborative of my argument.

(To be Continued.)

## Comparative Tests of Quartz Grinders.

EDITORS PRESS:—I was very much amused at Mr. Blanding's "bristling" at my request that he should confine himself to exact comparative figures in his tests of quartz machinery. "A little knowledge is a dangerous thing," he says. Well, let him use it rightly, and there is no particular danger for him. He puts me down as "evidently of the old, and probably of the foreign and unprogressive school." He is wide of the mark. "Old Man" is a full-fledged American of the progressive order. Mr. B. doesn't like my writing over a *nom de plume*. It is not the author (Mr. Blanding for instance) that is so material. It is the facts and brains presented that interest the public. Mr. B. dates his experience back to 1865. "Old Man" can go him just 15 better—to 1850—and knows exactly what he is talking about when it comes to gold or silver mining, or any and every class of mining machinery, but doesn't know what improvements Mr. B. ever suggested for quartz mills.

It is not of interest to the public for me to bandy words as to our comparative work with mills. Were I to do so Mr. B. would be honest and acknowledge himself beaten. As a mining man I have nothing against Mr. B. (according to his experience; far from it), but if he had commenced when "Old Man" did he would know more about primitive stamp batteries, and how to appreciate the present ones.

Go it, young man, but don't scratch your back against the rail fence any more. Take things calmly; argue points.

THE OLD MAN OF THE MOUNTAINS.  
Sonora, Tuolumne Co., Cal., July, 1886.

## Tellurides of Gold in Tuolumne County.

EDITORS PRESS:—Two lots of ore from the Garrett mine, on Bald Mountain, near this town, lately tested by me, gave such high results that it occurred to me that it might interest your readers to learn the figures. This is the mine producing the tellurides of gold to which I called attention some months ago in the columns of the PRESS, and which were made known by myself to exist in this mine and the Neale mine.

The two lots tested were amalgamated and all free gold removed; the tailings or residue then closely concentrated and the concentrates treated with the following results:

The first sample of 10½ pounds gave ¼ of 1 per cent telluride of gold. It yielded at the rate of \$23,368 per ton of tellurides.

The second sample of 93 pounds showed a yield of \$3.22 in free gold and ¼ of 1 per cent telluride of gold closely concentrated. The treatment of the tellurides from this lot gave a yield of \$27,500 per ton of tellurides.

The tellurides are found to exist in mines located at several points along the major axis of Bald Mountain, and lately I have also detected it in paying quantity in three mines on the mother lode, near Jamestown, in this county.

LOUIS BLANDING.  
Sonora, Tuolumne Co.

## A New Safety Cartridge for Coal Mines.

A new safety cartridge for use in coal mines where it is not safe to blast with gunpowder has lately, says *Engineering*, been introduced in Germany by D. Kosmann, of Breslau. Its action depends upon the rapid liberation, in the bore-hole, of a large quantity of hydrogen gas, the pressure resulting from which forces the coal or rock asunder. The hydrogen is liberated by means of the action of sulphuric acid upon very finely divided metallic zinc. For this purpose, Dr. Kosman takes the bluish-gray powder that forms in the condensers of zinc distillation furnaces, and which consists of a metallic zinc that has not been condensed to the liquid form, but results as a powder or as a more or less spongy mass. There is a small amount of oxide mixed with it, but for all practical purposes it may be considered as metallic zinc. The cartridge consists of a glass cylinder, narrowing to a neck, and being also contracted at a point below the neck, so that the cylinder is divided into two portions, communicating through a contraction whose opening is from 8 mm. to 10 mm. The contraction is so placed that the two parts of the cylinder are to one another in cubic capacity as 1 to 4, the smaller part being near the neck of the cylinder. The lower or larger division is filled with sulphuric acid obtained by diluting the chamber acid of commerce with an equal volume of water. The contraction is then closed with a stopper of rubber or cork, and in this condition the cylinder is handed over to the miner. The hole being bored ready in the coal or rock, is well clayed over inside, in order to close any cracks or cavities through which gas could escape. The upper part of the glass cylinder is now charged with the zinc powder, and an iron rod is laid in, passing through the zinc and resting upon the stopper in the contracted part of the cylinder. The neck of the cylinder is then tightly plugged with clay, and it is laid in the hole which is then also well tamped with clay, the iron rod passing through both these clay stoppings, and projecting some little distance beyond. In order to "fire the shot," the miner strikes the iron rod with a hammer, so as to drive in the stopper in the contracted part of the cylinder, or to break the glass at that part. In either case, the acid at once runs in among the zinc powder, and a very rapid evolution of hydrogen takes place. The iron rod is not uniform in thickness, but conical, being thicker toward the outside, and this increase of thickness is considerable, so that when the rod is driven in, it keeps tight in the clay stoppings and prevents any escape of gas. The inventor gives figures to show that a cartridge 180 mm. long and 25 mm. in diameter, taking a charge of 50 cubic centimeters of acid and 12 grams of the zinc powder, will give rise to an evolution of gas equal to 3.37 cubic meters at ordinary barometric pressure, and that the compression of this volume of gas into a space of 90 cubic centimeters means a pressure exerted on the sides of the hole equal to some 37,000 atmospheres. The pressure is obtained rapidly, but not so rapidly as to in any way endanger the man who drives in the rod. He has plenty of time to get away before any coal or rock comes down. It does not appear that these cartridges have yet had any thorough trial in practice, but much is expected of them, and the making of the cylinders has been entrusted to a large firm that will insure their being good and uniform. The cost of each "shot" will be from one penny to three half-pence, according to the size of the cylinder and charges used.

A GREAT GOLD MINE.—A great mining company is the one which owns the Homestake, at Lead City, three miles from Deadwood. The mine employs 3600 men. It is an extraordinary vein, 300 feet wide, a decomposed talcose green slate running \$8, and saving \$7.50 on plates. The mine was bought in 1875 for \$100,000 by Geo. Hearst, the lately appointed Senator from California. It was then stocked through Haggin & Tevis at \$2 per share, 100,000 shares, and has paid \$3,750,000 of dividends. There are over \$700,000 in the treasury. The stock has recently been increased 25,000 shares, thus there are now 125,000 shares in all. The increase was made for purchasing additional property. This mine pays \$50,000 a month dividend, and an extra Christmas present of \$1 per share. There are 60 miles of water ditches and 70 miles of wood roads. The wood cars are emptied on the hillside above the mill. The chute is so built that the wood piles itself up in front of the mills and thus requires no more handling. The four mills, 580 stamps, are reducing 1750 tons of rock a day. Two hundred stamps more are to be added. There is ore enough in sight, it is calculated, to last 30 years. The ore in the vein for 300 feet in width is worked like an open cut, the face of which is now 500 feet high. It is undercut and blown out and thus continued upward. In this ore body itself there is a 10-foot vein which mills \$60 per ton. It is used to average the balance. It is free milling, remarkably free. There is no stock swindle in the management, which is also managing the Ontario of Utah, that has paid \$7,000,000 and is paying yet at the rate of 75 cents a share a month (100,000 shares), also manager of the Anaconda mine and mill at Butte City, Montana. The mill was shut down a short time for alterations, but is again in operation.

## Dip and Underlie.

The "dip" of a bed is, as every one knows, its inclination downward, measured by the angle between the plane of the bed and the plane of the horizon. The normal position of a bed is horizontal, so that the measurement of its "dip" or deviation from this normal position is naturally and necessarily made from the plane of the horizon.

In metallic mining, however, another term, conveying a different idea, is commonly used in practice, and the inclination of a bed or vein is spoken of as its underlie. This is a well-known and commonly used term; but nevertheless, its true meaning—the one in which it has been invariably employed—seems to have been misunderstood by geological writers, who use it as a synonym for dip. Even so thoroughly practical a geologist as Mr. Beete Jukes defines "underlie" as the "inclination or dip of a vein or fault;" and it is not unusual for geological writers to say that a vein underlies at such and such an angle from the horizon.

But the real meaning of the word "underlie," as applied by miners to a vein or lode, is just the converse of this—for it is employed to express its deviation from a vertical plane. The normal position of veins—conversely to that of beds—is vertical; and consequently it is natural to measure their deviation from a vertical plane. Speaking of a vein, a miner will say that it has very little "underlie" if it is nearly vertical, and that it "underlies" very much if it deviates considerably from a vertical plane. And this is not only the sense in which it is at present universally used in practice, but it is also the sense in which it has ever been used and even in books until recently. In Pryce's *Mineralogia Cornubiensis*, "underlie" is defined as "the deflection, or deviation of the fissure from its perpendicular line;" and in Thomas' "Report" it is also calculated as "the angle of inclination from the perpendicular."

Therefore to say that a vein or lode "underlies" so many degrees from the horizon is to state a contradiction in terms—that is, the "dip" of the vein, but not its "underlie." In fact the "underlie" is the complement of the "dip," and vice versa.

It may be considered that a distinction of this kind is unimportant, but such is far from being the case. In Cornwall, and in numerous districts where the Cornish nomenclature has been adopted, the inclination of a lode is expressed by the length of base corresponding to one fathom in perpendicular depth, considering the line of inclination as the hypotenuse. Thus one lode (A) "underlying" 14° (or "dipping" 76°) is said to "underlie" 1' 6"; and another (B) "underlying" (or "dipping") 45°, is said to "underlie" 6". Such a mode of expressing the inclination of veins is not only clumsy in itself, but it is incapable of that ready determination by which an angle can be at once measured by a clinometer; and it besides encourages a want of accuracy.

Yet with all these disadvantages, even this system is more convenient than that of expressing the inclination in degrees from the horizon—clashing as it does with all our conceptions of metallic veins, which naturally refer to, and express themselves in, the amount of deviation from the normal vertical position. Thus, in the cases given above, of lodes A and B, we involuntarily attribute the greater deviation to B; and consequently when we say that lode A only underlies 1' 6", while lode B underlies as much as 6", the numerical expression of deviation is in the same sense as our natural conception of it. If, on the contrary, we say that lode A "dips" as much as 76°, while lode B only "dips" 45°, the numerical expression of the deviation is contrary to our conception of it. Hence, notwithstanding its clumsiness, it is more convenient in practice to express the inclination of a lode by the length of the base subtending the angle of the "underlie," than by the complement of this angle, or the angle of the "dip"—particularly in comparing the inclination of two or more lodes—inasmuch as the one conveys a direct numerical expression in accordance with our conceptions, while the other does not.

COAL IN THE TEMESCAL MOUNTAINS.—A splendid vein of coal was discovered in the Temescal mountains about five or six months ago by H. A. Bradley, the well known prospector of this vicinity. A shaft has been sunk on the vein (which pitches at an angle of about 45°) to a depth of about 40 or 50 feet, which presents a fine vein of merchantable soft coal about 12 to 16 inches in thickness with plenty of promising sand-rock in the foot wall and a ceiling of shale which in our opinion is heavily charged with petroleum, as a small piece will burn a steady light for fully half an hour. This valuable mine is located about 17 miles from Riverside and within plain sight of Arlington avenue. A surveyed line of railroad runs within about one and one-half to two miles of the mine and it is fully expected that the road will be in full running order inside of four or five months. Our townsmen, Frank Ryan and Charley Lockwood, have interested themselves in the coal mine and they promise some good developments as soon as arrangements can be made to develop the property.—*San Jacinto Register*.

## Another New Mining District.

Mines on the Moses Reservation.

The recent order of President Cleveland, throwing open the Moses reservation to public settlement, will add another new mining district to the many which radiate from Spokane Falls as their point of supply. Besides the mineral productiveness of this new and almost unexplored region, its inexhaustible soil and vast area of grazing land, of which those who have inspected them speak in terms of the highest appreciation, must tend to make agricultural and mining developments associate partners in the same firm, the one the handmaid of the other, with such reciprocal interests and mutual expectations as to augur very flatteringly for the permanency and progress of the country.

The Spokane Falls *Miner* says: The Moses reservation lies north and west of the Columbia river and embraces 2,243,040 acres of land. It lies in the western part of Stevens county and extends from the Okanogan river to the summit of the Cascades, and from Fort Chelan to within 15 miles of the British line. A portion of the country immediately south of it was thrown open in February, 1883, and those who prospected here have been long and eagerly waiting the executive order which would permit them to enter this promised land from which they have been too long debarred. It should be added here that the Okanogan country is distant in a northwesterly direction about 130 miles from this city.

A gentleman whose name we could not learn, but who has, for several years past, been attached to the reservation in the capacity of farmer, had kept himself thoroughly posted on the topography of the reservation and quietly explored it for mines which he dared not then, under the law and the circumstances, locate, was the first to drive his stakes on a mining claim. Being absent from the reservation at the time it was declared open, as soon as he learned that such was the case he rode day and night from a point in the vicinity of Colville till he reached it. The last night's ride was a weary and fatiguing one, but without resting he proceeded to the spot, well known to himself and, as he thought, to no others, began stepping off his 1500 feet and had scarcely finished driving his stakes when, as daylight began peering through the half-sleepy eyelids of the morning, he discerned five horsemen approaching him. He was surprised to learn that their errand was to locate the same claim which he had just allotted himself. Disappointed but not aggrieved, the five breathless prospectors immediately set out to locate several mines near by, whose existence they had a year previously ascertained. Since then several parties have gone over to the Okanogan and have returned or sent back glowing reports of that country's mineral promise. Among them is Mr. A. E. Benoist, one of the discoverers of the Old Dominion near Colville. Mr. Philip Pierce, of Colville, returned from the new district some two weeks ago and he reports that the country is pleasantly accessible to the prospector, that ledges have been discovered which measure from 8 to 30 feet face and which assay \$10 in gold and \$50 to \$90 in silver.

As was to be expected, a moderate stampede of miners from the South Fork and Colville districts set in, and it is safe to say that at present writing there are 100 prospectors striking heavy blows, bidding the treasures of Okanogan come forth from their lurking places. Thus it will be seen that another mining camp of great possibilities has been added to the list of these either surrounding or not far distant from Spokane Falls.

As the prospector moves, the area of mineral wealth enlarges and beckons back to civilization and capital to come and occupy, explore and exploit. To us, who live near the scene of these developments, they have ceased to be a matter of wide-eyed surprise. The fact is, we are growing so used to reports of rich districts that we have learned to feel a keen sense of disappointment if they are not reported at frequent intervals, since the richness, stability and universality of leads which gridiron the Colville, Chewelah, Pend d'Oreille and South Fork districts have imbued us with a *nil admirari* matter-of-fact placidity of soul, which subsequent discoveries can neither shake nor disturb.

Time was when California was presumed to be the only territory rich in the noble metals. Then came the Pike's Peak excitement of 1857, which ushered Colorado into a slow and feebly recognized prominence, and it required nearly 20 years thereafter when the Leadville, Gunnison and San Juan countries brought the Centennial State to the front rank as a silver-producing region, to convince the country that California was not the only locality where silver and gold could be found abundantly and everywhere.

Nevada, too, served a good purpose in demonstrating the fact that practically the mineral belt of the Pacific Coast knows neither metes nor bounds; that it is impartial in its universality, and that its prodigality was not confined to California, for it is doubtful if even Peru, since the day when a hundred llama loads of gold and silver were carried down the Andes to ransom the imprisoned Atahualpa, could compare with Nevada's mineral productiveness. The same can be urged of Utah, New Mexico and Arizona to show that new Californias are springing up every few years on this coast under the magic touch of the prospector's pick. And

now comes Eastern Washington, the latest but probably not the last, to unfold the wealth of her neglected mountains and streams. Until within the last 15 months nothing was known of her wonderful mineral possibilities. While other Territories and States on this coast and east of the Rocky mountains, including such Territories as even Dakota and Wyoming, have passed local laws regarding the recording of locations, assessment work, miner's liens, abandonments, water rights, etc., the statutes of Washington Territory are yet unvetted with legislation of this character. She sat secure in the blissful certainty that her only wealth consisted in her rich agricultural and stock-grazing acres on her eastern confines and in the lumber, coal and iron products of Puget Sound. She has been almost unconscious till a very recent period of the mineral wealth on which her future sits enthroned. She was, so far as her knowledge of the entombed gold and silver in her hills went, *magnas inter opes inops*. But a new era has dawned upon us. Stamp mills, crushers, smelters and concentrators are coming into the country. Prospectors are swarming in every direction, making new finds daily; flumes and ditches are carrying in their swift currents golden sands and golden nuggets; manufacturers of mills, explosives and mining supplies have their agents in every camp, till our Territory's mineral possibilities have become recognized potentialities, and the day is not a remote one that will witness the testimony in favor of Washington's pre-eminent mineral wealth given by individuals whose Nazareth has been California and California alone, beyond whose boundaries "no good can come," just as the man of 40 years of age now admits that the geography of his youth was a delusion and a gross error, when it taught that the Great American Desert was a blotch on the map, that it was a wide gap of hideous sterility located midway on our continent, and inhospitable on account of its unproductiveness; yet to show how little was then known of its resources, this same desert embraces to-day the prosperous, fertile States of Kansas and Eastern Colorado, to laugh to scorn this egregious blunder of the map-maker and the silly, rustic omniscience of those who believe that nature has set her bounds to all discovery and will so keep them, unless they are permitted to lazily participate therein.

## The Idaho Mine.

A Very Profitable Gold Producer.

The Foothill *Tidings* (Nevada county, Cal.) says the Idaho is located on what was once known as the Eureka ledge, and the ledge was so named because the Eureka mine was the first on that ledge to be worked. The old Eureka took out about \$5,000,000 worth of gold, before the pay chute went across the line to the east and into the Idaho's ground. The ledge is now generally called the Idaho, because the Idaho mine has overshadowed the memory of the old Eureka. Legally, however, the ledge is still the "Eureka." The Idaho location was made and the mine named in 1863. The mine is east of town, about two miles distant, and it is on the left bank of Wolf creek, a little stream that runs over and near very many rich ledges and will be the main distributor of the new water power. The Idaho's location is 3100 feet on the ledge, and the shares of capital stock are 3100 in number. In 1865 the mine passed into the ownership and management of the present company; Edward Coleman became the superintendent. The management has been the very best. The mine has yielded something over \$8,000,000, of which \$3,750,000 have been paid to stockholders as dividends, the balance being paid to a small army of laborers and men furnishing materials. The mine is now opened to 16-foot level, and the shaft is down to 17-foot level, making an opened mine 1600 feet of perpendicular depth, or on incline 2200 feet, with drifts and levels. On the 1st of June, 1886, the 200th dividend in number was paid, the dividends being monthly as a rule. Some four or five monthly dividends have been missed in the 17 years of dividend paying, and that was when much so-called "dead work" had to be done.

In the later days of the working by steam power, the Idaho mine burned about 8500 cords of wood in a year. Then it was that the Coleman Bros. (we look upon both Edward and John Coleman in the light of managers of the mine) determined to reduce expenses in the matter of power. Some of the stockholders favored "gonging the eye out of the mine and letting her fill up with water," as they expressed it, but the Messrs. Coleman, backed by a majority of shares of stock, made the change at an expense of \$46,000. This proved a good investment, since \$35,000 a year is saved by the water power, and work goes on and dividends continue and the army of Idaho workers are still supporting families and maintaining happy homes.

NOVEL METHOD.—Says the Albion (Idaho) *Times*: J. J. Storey, of the Minidoka ferry, has invented a new process for saving gold on Snake river. He has a plate of iron arranged, heavily charged with mercury, which he attaches to the ferry-boat and allows it to float on top of the water. By this novel method he has saved a large quantity of amalgam, but as yet he has not ascertained its quality. It has long been the theory of many that most of the Snake river gold floats with the current on the surface of the water.

## Side Lines of Mining Claims.

The man who attempts to amend the present mining laws so they will be satisfactory to every portion of the country is making a bed of nettles for himself. An illustration of the fact can be seen in the reception which the mining community has given to the amendment to the present law governing the location of lode mining claims, introduced in the House by Representative Symes.

Of this the Denver *Tribune-Republican* says: The amendment proposes to give to mine-locators all the ore within their boundary lines "extended downward vertically." It puts a mining claim on the same basis as other lands, the owners of which hold everything within their boundaries "between the heavens and the center of the earth." The amendment also provides that a claim may equal, but not exceed, an area of 20 acres; that when the location of adjoining claims will permit, the form of a claim shall be a parallelogram, and that its length shall not be more than one-third greater than its width.

There are some portions of the country, like Leadville and Aspen, where the apex fiend is unpopular, in which the proposed change in the law is favorably considered. In counties like Boulder, Gilpin and Clear Creek, where the veins are acknowledged to be fissures within the meaning of the law, the proposed change is not popular. How it is in Eagle county, about Red Cliff, we cannot say. It is certain, however, that if the law had been as it is now proposed to make it at the time the first claims on Battle Mountain were located, a large part of the rich quartzite deposits since discovered would belong to the owners of those first locations. These facts may have some influence on the opinions of men in that section upon apex and side line problems.

If the law should be amended as proposed, it would have a rather peculiar effect upon the size of claims in counties. Where lodes and claims are thick on every hill, it is generally the case that only a narrow strip of ground can be found between locations. Supposing that a prospector should find a lode on a little strip of vacant ground, say 100 feet wide, the length of his claim would be limited by law to 133½ feet. If the discoverer found entirely free ground, the length of claim which he could take would be 1077 feet, and the width 808 feet. If the law is to be amended, would it not be better to limit the length of a claim to 1500 feet and its area to 20 acres, striking out the provision as to the proportion of width to length? Is it not possible that 20 acres is too much to include in a location? Is there any necessity of modifying the law, except in respect to the apex question? Is there really any necessity for modifying it at all? All these are interesting questions, upon which there is a wide difference of opinion. Any amendment which is now made cannot affect prior rights. It cannot relieve Aspen of the apex ghost that is paralyzing her industries. The present provisions of the mining acts are understood. The courts have passed upon most of the knotty questions and precedents are established. It is a serious question now whether the proposed amendment would not create more litigation than it would prevent in the future.

It is true that the present law is construed by the courts to apply to a class of mines to which it is not believed it was ever intended to apply. It is, perhaps, rather a fortunate thing that, as a general rule, the juries have not agreed with the courts. At the time the present law was enacted, the late J. B. Chaffee was a delegate to Congress from the then Territory of Colorado. The bill, as originally introduced, confined every claim-owner to his vertical side lines, and the amendment allowing him to follow his vein beyond the side lines was made at the instigation of Mr. Chaffee. Mr. Chaffee was requested by many to secure the amendment. We have a distinct recollection that among mining engineers it was not supposed that the law would ever apply to that class of deposits known as beds, to which the courts have made it apply. However, fissure veins were the only ore deposits known in Colorado, and the question received little attention. It would, perhaps, have been better if the amendment had never been adopted, and if the court construction is to forever remain as unchangeable as the laws of the Medes and Persians, it may be that Representative Symes' amendment is a good one. In discussing the subject, Colorado miners should remember that the United States laws are made for the entire country, of which this State is only a portion.

LEASE OF MINE WITH PRIVILEGE OF PURCHASE.—In the case of *Settle vs. Winters*, the Supreme Court of Idaho has quite recently decided that where parties contract for a lease of mining property with the privilege of purchasing it within a fixed time named in contract, and the character of the property (such as of mines generally) is such that it is liable to sudden fluctuation of value, time is of the essence of the contract. No matter if the lessees and would-be purchasers have paid a considerable portion of the proposed purchase money, it has been out of the ore of the mine, and unless all the purchase money is paid within the prescribed time (or time of option), the right of purchase is extinct at the expiration of the time, and the original owners are entitled to hold their property.

## Quartzite Deposits at Red Cliff.

In an article on this subject, the Denver *Tribune-Republican* says: As described in previous letters, the quartzite on shoots occur in trough-like cavities which are denuded of ore as work progresses, so that few, if any, reserves of ore are left standing in the mines. In judging these mines many new features must be taken into consideration, such as continuance of ore, cheaply mined, evidences of which must be had from shipment records rather than from ore in sight. Such records are to be looked for and found in claim after claim developed along the entire belt, as now opened. In the quartzite impecunious miners have suddenly acquired good bank accounts, because pay has generally rewarded their efforts near the point where work was begun and before debts were possible, and all subsequent expenditure provided for in advance, by the richness of the ore already mined. Such mining as this is rare, especially in view of the many instances in which one man's experience or luck has been identical with so many others. It is also a fact that there has thus far been no boom, although the foundation for one, upon merit, has never been greater, if we consider the amount of money realized as profit over expenditure, the rapidity of shipments after discovery, and the scope of country seamed by the mineral-bearing quartzite. But the quartzite mines are not the main source of mineral wealth. The carbonate deposits in the lime have for several years ranked Red Cliff second to Leadville in the field of desirable smelting ores, and that supremacy is liable to continue indefinitely. Some of the old producers, such as the Belden and Eagle Bird group, have been abandoned on account of company difficulties, and the erroneous notion that when the sulphide zone was reached the further search for pay mineral should be abandoned. The Black Iron mine has put this theory to rout and demonstrated that good ore, and of a carbonate variety, too, may be found beyond the sulphide barrier, and it is quite probable that these properties may again be started up. The Iron Mask mine is a finely developed property, with massive mineral reserves blocked out and a daily output of 80 to 100 tons from exploit work alone. The placement of a heavier plant of machinery has retarded shipments for a short time. These two mines, the Black Iron and Iron Mask, show the greatest depth into the mountain—1200 feet—and the heaviest ore reserves. New discoveries are of common occurrence, and the present year will advance Eagle county to a higher standing in the list of producing counties than she has hitherto attained.

PRICE OF SILVER.—Bar silver has again gone lower than ever, is now the lowest on record. It is a little curious that this continuous decline follows close upon the discussion in the British Chamber of Commerce. It was openly and warmly argued in that debate that the continued fall in silver would tend to compel wheat and cotton producers to supply England at low rates. But other and abler men showed that England was losing in the process quite as much as anybody else. A banking house here avows the belief that Germany has been selling part of its store, and that gold drawn from this side went to pay for the silver sold, but behind all the other explanations and more important than all, is the fact that all talk about attempts to force silver into use only tends to discredit the metal and to prevent its use. A prominent Wall street bullion dealer said: "The *Tribune* a few weeks ago published a report from its London correspondent that Germany was selling silver, but not one of the three leading bullion dealers in London has even mentioned such a thing in the market circulars. Neither has either of the London financial newspapers nor any of the daily papers, so far as I could learn, alluded to Germany selling silver. Had such been the case it would undoubtedly have appeared in all the leading London financial papers, and our London house would have advised us at once. The only allusion I find respecting Germany and silver is what might be called an appeal in the London *Economist* to the German Federal Council to adopt the monometallist law passed some years ago by the German Parliament, and thus take from the German silver thaler its legal character. The decline in silver, in my opinion, was caused by the small demand for Indian Council bills. The latter in turn was also caused by the depression in trade and the widespread political agitation in India, together with the unsettled state of feeling between England and China regarding Burmah."

GOLD BULLION.—The receipts of gold bullion at the U. S. Assay Office for the past three days were over 1400 ounces, being the greatest amount ever received for that length of time in the history of the office. The value of deposits received from July 1st to July 9th, inclusive, was \$28,602.61, the heaviest amount ever handled in a like period at this office. The suspension of the transportation charges by the Government, thus saving a considerable expense to depositors, together with the satisfactory assaying done, is turning the tide of bullion business in the direction of Boise City.—*Boise City Statesman*.

## TABLE OF CONTENTS.

EDITORIALS.—The Tustin Ore Mill, 49. Mine Superintendents; Ore Deposits and Rocks; American Mining, 52. Foundry Notes; Mining Accidents; Petaluma, 53.

ILLUSTRATIONS.—The Tustin Ore Mill, 49. Bullion Furnace Room of the Lyon Mining and Milling Co., Dayton, Nev., 53.

CORRESPONDENCE.—Common-Sense Geology—No. 3; Comparative Tests of Quartz Grinders; Tellurides of Gold in Tuolumne County, 50.

MECHANICAL PROGRESS.—Automatic Machinery; A Boiler Furnace for Refuse Fuel; Helps do More Work; Hand vs. Machine-Cut Files; A Wasteful Engine; Lubricating Gears; India Requiring Iron and Steel, 54.

SCIENTIFIC PROGRESS.—A Solar Cyclone; The Luminosity of Flames; Seeing the Invisible; Self-Ignition of Greasy Cotton Waste; The Red Sunsets; Increase of Accidents from Lightning; Improvement in Bleaching; Lead and Platinum, 54.

ENGINEERING NOTES.—A New Method for Utilizing the Water-Power of Niagara; Wooden Water Wheels; Canals vs. Railroads; Railroad Building in Asia Minor; Coal vs. Wood, 55.

USEFUL INFORMATION.—Size of Rooms and Fitting of Carpets; A Hair-cutting Machine; Renewing Faded Inks; To Make Ink Spots Invisible; Utilizing the Milkweed; New and Cheap Evaporator; Dry Pocket Glue; Fire Extinguishers, 55.

GOOD HEALTH.—Doctors Disagree in Regard to What May be Trusted to Digestion; Imaginary Ills; Advantages of Low Ceilings; Iced Drinks for Dyspepsia; The Poison of the Scorpion; Insanity in China, 55.

MISCELLANEOUS.—A New Safety Cartridge for Coal Mines; Dip and Underlie, 50. Another New Mining District; The Idaho Mines; Side Lines of Mining Claims; Quartzite Deposits at Red Cliff, 51. Refining Copper Bullion Produced by Amalgamating Tailings, 53.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, Idaho, Utah, Colorado, Oregon, Washington, New Mexico, 56-57. MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 60.

## Passing Events.

Great preparations are being made in this city for the coming encampment of the Grand Army of the Republic. A large arch is being built, and many houses will be decorated on the line of march of the procession. Quite an elaborate program of events has been prepared.

The Legislature convened this week to consider the question of water rights and irrigation. Thus far very little has been done, and it is difficult to say what the result will be. It is hoped, however, that some settlement of the difficulties will be made, so that the large tracts of land requiring water for irrigation purposes may obtain it without paying large sums to monopolists of any class.

Machinery and men have been sent to Meadow Lake district, in Nevada county, to try once more to work the refractory ores there. So far there have been many failures, but those undertaking the new plan are hopeful of good results.

The strikes among the iron-workers in this city still continue, but it is hardly probable that they will be kept up much longer, as there are already signs of dissatisfaction among those ordered out, and they want to be at work again.

The chloriders at Reveille are getting out some very fine ore.

## Mine Superintendents.

The mining regions have suffered more or less from incompetent superintendents, and mine-owners have been losers for the same reason. Yet there is no rule or law to prevent a store-keeper, blacksmith or anybody else assuming the position and title if he can get it. Experienced mining men, of course, always look out to get an experienced superintendent for their property; but those fresh in the business have no distinct authorized class to draw from. There are no examinations required and no certificates of competency are issued either by Government, State or association. If there were, people would be better protected, and only those fit for the position would be able to obtain it. No move in this direction has been made in this country thus far, however, though in some European countries mine superintendents have to be commissioned. In England this is the case with coal mines; but, strange to say, not with metalliferous mines. But recently the metalliferous mine agents have been agitating this question and have held a meeting in London to consider a proposed amendment to the Mine Regulation Act, in the matter of granting certificates of competency to metalliferous mine superintendents.

The chairman, in opening the meeting, said he thought it was time something should be done to raise the status of metalliferous mine agents. It was, however, necessary that some one should take the initiative, and for this purpose the meeting had been called, which he sincerely hoped would be followed by many others in different parts of the country. At present a tinker, tailor, peddler or poacher could be appointed manager of mines. He sincerely hoped the meeting would support a resolution in favor of Dr. Foster's proposed amendment, as he felt certain if made law the status of the mine agent would be considerably raised.

Another gentleman briefly related the steps that led to the calling of the meeting. He fully and heartily concurred with everything said by the chairman. The granting of certificates as proposed would tend to raise the status of mine agents, open the door of promotion to the intelligent miner through merit, give employment to the deserving, keep out quacks, and benefit the industry in all its parts.

Still another thought it was high time certificates were granted, as now many an agent gets his office more by being in favor with some of the directors than by any qualification in him for the work.

It was then agreed—"That a resolution in support of Dr. Foster's proposed amendment should be sent to the Home Office, Dr. Foster, the members for East and West Denbigh and Flint, and also that the resolution be sent to the centers of mining in Cornwall, South Wales, Shropshire, and north of England, with a recommendation to bring the matter before the mine agents in their separate localities."

## Ore Deposits and Rocks.

The ore deposits in the different points of Nevada, carrying gold, silver, lead, copper and other useful minerals, are not limited to rocks of any geological age. The Archean granite of Austin, the Paleozoic strata of Eureka and White Pine, and the Mesozoic rocks of Washoe, are sufficient examples of this fact. The deposits occur in the mountains, as is usual the world over, and as the Nevada mountains are disposed in parallel ranges of course the mines occur in parallel belts. There is no perceptible tendency to the development of the same minerals at different points on the same belt, though there are no ore-bearing zones comparable in continuity with the gold and quicksilver belts of California.

In most cases it is impossible to determine the age of the deposits, yet there are many phenomena indicating connection between them and eruptive activity, according to Government geologists, and they are probably, for the most part, referable either to the post-Jurassic period of upheaval or to that of more recent volcanic eruption. The gold veins of this State are post-Jurassic, and the Idaho gold veins are probably for the most part of the same age. It is difficult to suppose that the physical conditions prevailing in Nevada during the same period were not attended with similar mineralogical results. The Comstock, however, is probably very recent, and a concomitant of volcanic eruptions in its immediate neighborhood.

Clarence King, in his "Explorations of the 40th Parallel," drew attention to the fact that no ore pebbles have been found in the Tertiary lakes of Nevada, and this statement still remains valid, so far as the exploration of the 40th Parallel is concerned. Nor are prospectors known to have found any indications of ore in these beds. The negative evidence is all in favor of the supposition that the deposits are mainly Tertiary, or post-Tertiary.

## American Mining.

Among the best characteristics of American mining practice may be mentioned the originality and ingenuity of the methods which have been adopted. In many cases, as, for example, the system of hydraulic mining, a new departure was made, and within a short time carried to an extreme point of development. In other instances modifications and improvements on foreign methods have been added to such an extent that their sources are scarcely recognizable. Another striking feature is the rapidity and execution and consequent saving of time and interest. It is true this has often been pushed too far; but it may be said, as a rule, that capital invested in precious metal mines in this country has always secured quick returns, if any. This is necessitated by the demands of investors who are seldom satisfied, when interested in precious metal mining, with the plodding methods which perhaps in the long run would be more profitable, and on which they would rely in any other branch of industry. Although undue haste must be condemned from an economic point of view, the spur has not been without its advantages on the technical side.

Still another feature is the boldness of conception of engineering enterprises connected with mining, and the large scale on which operations are conducted. As examples may be cited the ditch, flume and pipe system of the hydraulic mines, the daring feats in railroad engineering securing transportation from rugged mining districts, the extensive tunnel enterprises, and the very deep shafts fitted with pumping and hoisting machinery.

On the other hand, says Clarence King, the eminent mining engineer, it must be acknowledged that the attempt to rely on originality of plan to the exclusion of experience gained abroad has often resulted in failure. Novel processes and machinery which have been tried and condemned by foreign miners have sometimes been reinvented and experimented upon in this country with a failure which could have been avoided. The desire for immediate returns has been carried to an extreme and has entailed unnecessary loss. In remote districts freight is often hauled out of season at increased expense. Ores are treated at high cost and low percentage of metals saved in primitive mills and smelters, when such delay as would be caused by the erection of custom works, or the approach of railroads, would much more offset the loss of interest on unreduced ores. It should be noted, however, that mines worked with insufficient capital are obliged to adopt the hand-to-mouth system, in order to keep in operation at all.

A CORRESPONDENT at Cisco, Utah, in describing the blood agate fields recently discovered in that locality, writes as follows: The find has been fully examined and each day brings to light some new and strange formations of the stone, none of which have yet been classified by experts, and all of which are very beautiful. A contract has been let for cutting and polishing a lot of the stone, and it is soon to be placed on the market.

THE Nogales (A. T.) Smelter Company commenced operations on the 14th inst., and everything worked satisfactorily, the result of the day's run being ten bars of bullion. This is an event of great importance to that section of the country, as it will enable mine-owners in Sonora and also that section of Arizona to ship their ore to be reduced at Nogales, instead of shipping it to Denver or Pueblo.

THE furnaces in the Giant mill, Park Canyon and Nye county, are now doing good work and the ore is chlorinized up to between 85 and 90 per cent of its assay value.

ACCORDING to the Carson Appeal, a second shower of sulphur fell there Friday.

## Refining Coppery Bullion Produced by Amalgamating Tailings.\*

NUMBER 2.

## Furnace and Cost.

[On page 33 of last week's PRESS was given a diagram of the furnace for roasting bullion, and the description of the process was commenced on page 35. We herewith show a plan of the furnace-room, which adjoined the retort house, and continue the description.—Eds. PRESS.]

The floor in front of the furnace and around the sulphurizing kettle was covered with sheet-iron plates; elsewhere it was of matched boards. A track for the bullion and amalgam car ran from the mill through the furnace-room into the retort house.

The following amounts were paid out for constructing the furnace and furnace-house (in 1875):

## COST OF FURNACE.

Foundation:	
Preparing ground, Chinaman, 1½ shifts, at \$1.53	\$2.30
Hauling stone, 2-horse team 1 day.....	6 25
Masons, 4 shifts, at \$7.50 plus \$1.75 fare....	31 75
Masons' helpers, 6½ shifts, at \$1.53.....	9 04
Lime, 250 lbs, at 2.652 cents.....	6 63
	\$56 87

Superstructure:	
4930 common brick, at 1.972 cents.....	98 20
400 fire-brick, at 18.35 cents.....	75 41
819 pounds lime, at 2.679 cents.....	21 94
Hauling sand and clay, 2-horse team 1 day....	6 25
Masons, 18½ shifts, at \$7.58.....	140 25
Masons' helpers, 26 shifts, at \$1.53.....	39.78
	\$31 83

Iron Work:	
2 frames and slip doors.....	160 pounds
1 fire-door.....	155 "
Hearth plates.....	1695 "
Hearth-plate discharge cover.....	23 "
	2033 lbs @ 8c. 162 64

Drilling and fitting doors and plates with bolts	18 25
Patterns for doors, frames and plates.....	22 00
Blacksmithing and old iron.....	25 00
	227 89
	\$866 59

## COST OF FURNACE BUILDING.

Lumber:	
Rough, 4710 feet, at \$35 per M.....	\$164 85
Dressed, 487 feet, at \$65 per M.....	31 66
Shingles, 6750, at \$6.50 per M.....	43 88
	\$240 89

Hardware:	
1 keg 10d. nails.....	6 75
1 keg 12d. nails.....	7 00
1 gross screws, 1½ inch, No. 18.....	3 00
59 dozen screws, 1½ inch, No. 13.....	4 88
10 sheets iron, ½" x 3' x 10', 1708 lbs., @ 7.05c. 120 47	
	142 10

Paint:	
White lead and oil, inside work.....	5 50
Copper paint, home-made, outside work, not charged.....	
	5 50

Wages—Carpenters, Painters, and Helpers:	
4 shifts.....	\$6 00
1 shift.....	4 50
10 shifts.....	4 00
12 shifts.....	3 50
5 shifts.....	3 00
	23 50

32 shifts, at \$3.92.....	125 50
	\$513 49

## FURNACE AND BUILDING.

Labor, 88½ shifts, at \$3.95.....	\$349 52= 29 6 per cent.
Material.....	\$30 56= 70.4 per cent.
	\$1180 08=100.0 per cent.

## Roasting Base Bullion..

The usual charge of base bullion for this furnace was 400 pounds; but as much as 500 can be treated easily, while, owing to the way in which the bullion was supplied, the average charge for two years was actually only 384 pounds. Were the furnace running regularly, a normal charge would be about 450 pounds of calcined, corresponding to about 400 pounds of retorted base bullion.

The roasting process is conducted as usual, the manipulation requiring no special description. The bullion is brought to a bright red heat, stirred well, and moved several times from and toward the fire, so as to expose all parts equally to the heat.

When only one charge was roasted daily, the furnace being nearly or quite cold at the commencement, the operation occupied about 1 shift or 10 hours. Two charges were roasted in 1½ shift, and 3 or even 4 charges in 24 hours, the last occurring when the furnace was hot at the start. The roaster was able (except in the last case), also, to sift the charge previously roasted, and to attend to other matters which did not take him away from the furnace building. The roasted material was passed through a No. 10 wire screen, the lumps averaging 1.29 per cent.

The average gain in weight by this operation was 5.4 per cent of the charge, corresponding to 6½ per cent of the retorted bullion.

The average gain in weight (two years), by both calcining and roasting, reduced to terms of retort bullion, and deducting all lumps, was:

	Per cent.
By calcining.....	17½
By roasting.....	6½
Total.....	24

\*Read before the American Institute of Mining Engineers by A. D. Hodges, Jr.

The oxidation of the last remaining percentage of metallic copper in this material would appear to be in part a function of lime. Repeated attempts were made to shorten the operation by crushing finer, constant stirring and the introduction of air through the fire-bridge and the arch and into the fireplace, but no material advantage in this respect was ever obtained, the last one or two per cent of copper oxidizing very slowly.

One man per shift, selected carefully for the place, did all the roasting. The wood fuel consumed was an average of 0.271 cord per shift of 10 hours, or 0.216 cord per charge (of all kinds) actually roasted. These figures are derived from the work done in eight months, when 393 charges were treated in 313 shifts, with a consumption of 85 measured cords of wood, or one cord to 1493 pounds of retort bullion. In another year (an unfortunate one in some respects) 86 cords of wood were charged against the furnace, or one cord to 1040 pounds of retort bullion. Part of this wood was used elsewhere. Although fuel was dear on the Comstock, it was used most wastefully everywhere. The easiest practical way to check this waste was to contract the size of the fireplace to the smallest allowable limits.

#### Sulphurizing.

To this process came the dense material of all kinds—the white bullion, base lumps and all the assay bars. The sulphurizing vessel was an old sulphuric acid parting kettle of cast iron, three feet in diameter, provided with a cast iron cover, which, when the kettle was charged, was luted and bolted fast to the kettle flange. The kettle was set in a low, brick fireplace of the simplest construction.

The kettle was charged with whatever metal was on hand, as much as 450 pounds being put in; mixed with this was 18 per cent of sulphur. For the sake, simply, of facilitating the removal of the mass when sulphurized, layers of thin wood (generally old barrel staves) were placed throughout the charge. The cover was fastened down, and a small fire of chips or any refuse fuel was maintained under the kettle for four or five hours. No particular attention was paid to the length of time of firing (the fuel costing nothing), as the roaster generally charged and fired the kettle during his work on the bullion furnace, and the whole operation of removing the cooled charge, and sulphurizing the new one, was done in one shaft. After the process was finished the cover was removed and the charge left to cool until the next morning.

The sulphurized material formed a black or grayish-black mass, the lowest part fused, the upper and larger part retaining the general form of the pieces put in, often showing pretty, needle-like crystals on the surface. It was removed with hammers and cold chisels, being ductile while warm, but brittle when cold, weighed, and sent to the Chile mill to be crushed. The amount of lumps, after crushing, that would not pass through a No. 20 screen varied according to the method and length of firing, and the size and density of the pieces charged into the kettle. With only retort bullion or small base lumps, and a gentle and long-continued fire, the whole charge was sulphurized so completely as to crush in its entirety. On the other hand, owing to the repeated melting of samples for assays and tests, solid bars weighing five or six pounds or more were frequent, and these were sulphurized only after passing several times through the kettle. All lumps from crushing were put into the roasting kettle.

A small, varying amount of sulphur escaped during the process. On an average 16.7 pounds of sulphur combined with 100 pounds of bullion. The total amount of sulphur used was 21 per cent of the original weight of the bullion at the Lyon mill (1876-7) and 20 per cent at the Omega mill (1878).

The expense of sulphurizing at Dayton con-

sisted simply of the one item of sulphur, as the labor employed being so small was charged for in other work, and any extra fuel possibly used was charged up to roasting.

#### Foundry Notes.

Business continues dull at the foundries in this city, there being very few large orders on. There is more or less small work, as is usual at this season; but big jobs are scarce, and, what is more, they will be scarcer if the era of strikes keeps up.

There are signs, however, that the present strikes will not last much longer. It was first thought that the molders at the Risdon would follow the boiler-makers out, but they did not do so. The machinists, molders and pattern-makers, numbering between 400 and 500 men, were ordered out by the Federated Trades; but as their unions are represented in the Iron Trades Council, the constitution of which provides that no union shall go on strike unless ordered by a majority vote of the unions represented in said council, they refused to obey the order and continued at work. The boiler-makers have received no assistance from the Federated Trades. At the meeting of the Iron Trades Council on Monday night, they decided to take no action in regard to the boiler-makers' strike, for the reason that as the boiler-makers had come out at the request of the Fed-

was because they were asked to work on boilers belonging to Spreckels & Co., who had been boycotted by the Federated Trades. The Spreckels have had upward of 100 new boilers built in this city in the last few years. There are 16 in the Braanan street refinery, 22 in the Potrero, 28 in one house at the Hawaiian Commercial, besides what are in the mill; then there are Hakalau and other plantations, besides some other manufacturing institutions in which Mr. Spreckels is interested in this city. Also three tugs, including the first *Relief*, which was lost. Most of them were built by the Risdon Iron Works and many of them by the very men who have now struck. The miles of large iron pipe that conveys water to the Hawaiian Commercial Company was made by the boiler-makers of the Risdon, and the wages paid for bending, pinching and riveting the iron for this job amounted to over \$50,000.

#### Mining Accidents.

C. I. F. Zeilian, while working in the quartz mill at Poverty Hill, had his left hand caught in the machinery, crushing the last two fingers and a portion of the left hand. He came immediately to town to Dr. Frisius, who found it necessary to amputate the fingers.

While working in the Black Oak mine, near Soulsbyville, Tuolumne county, says the *Union-Democrat*, a sliver of steel from his pick struck

#### Platinum.

Platinum has been found in small quantities in various parts of the country, associated with free gold in placer deposits. Indeed its distribution has been almost co-extensive with these deposits, but in most localities the quantity is altogether too small to admit of economic working, and it is only from the placers of the Pacific Slope, north of the Central Pacific Railroad, where it has been produced in merchantable quantity. The following are the localities at which most of the platinum heretofore collected in California has been procured: Hayfork, a branch of the Trinity river, occurring here in fine grains, mixed with the placer gold, to an extent sometimes sufficient to reduce the value of the gold by 8 to 10 per cent; on the north fork of the Trinity platinum is less plentiful, but occurs in larger grains, the largest pieces ever found weighing between two and three ounces; in Butte county, in the hydraulic mines around Cherokee and Oroville, occasionally for nine parts of gold found in this locality one part is found of platinum and its allied metals; in Mendocino county, in Anderson valley, Navarro river; in Plumas county, on the principal forks of Nelson creek and at Badger and Gopher hills; on the Salmon river, and in the beds of the larger streams in Sierra, Trinity and Del Norte counties; on the ocean beach between Capes Blanco and Mendocino; on the Tuolumne river. Going farther north the amount of platinum increases. On the Oregon coast the proportion of gold to platinum in the placers is sometimes five to one, and in rare instances the amount of platinum equals the gold. Platinum has been reported as occurring in Idaho, and in the Black canyon and on the Agua Fria, in Arizona, though the occurrence in the latter Territory is not well authenticated.

The most important foreign sources of platinum are the hydraulic mines at Nizhne-Tagihlsk and Goro-Blagodat, in the Ural mountains, where the ore is found with chrome-iron ore in serpentine. About 80 per cent of the world's production comes from this source. Next in importance are the gold washings of the Pinto, in the province of Antioquia and the headwaters of the Atril river in the United States of Colombia, where it is bought by the traders in inland towns and sent to Buenaventura, thence to Paris; about 15% of the entire product comes from this source. In Brazil the ore

is found in the province of Minas Geraes, associated with syenite. It is found also in the Natos mountains in Borneo, in Hayti, Peru, India, Australia, and in the sands of the Chaudiere river in Quebec. It has been noticed lately according to Williams' "Mineral Resources," in a quartz vein impregnated with gold-bearing iron pyrites, which was struck when deepening the shaft of the Queen of Beauty gold mine, Thames gold district, New Zealand. The interest in this deposit lies in the fact of the extreme variety of platinum ores in place.

THE Elko *Independent* says: The demand for laborers in this place and vicinity is greatly in excess of the supply, and 40 good men could find ready employment at good wages here by applying for work. Help is wanted to unload cars, also in the hayfields and in the mines of Lone Mountain. We are also informed that a number of men would be furnished steady work in the country round about Tuscarora.

THE supervisors have contracted with E. O. Uren, county surveyor, to make an official map of Placer county. The price for the work is to be \$850. The map will be about 8x4 feet in size and will contain every road, ranch, stream, and land-owner's name in the county.

THE Monarch mine, Indian Springs district, nine miles northeast from Dayton, owned by parties in Dayton, is being prospected at the depth of 50 feet, crosscutting the ledge,

BULLION-FURNACE ROOM OF THE LYON MILLING AND MINING CO., DAYTON, NEV.

erated Trades, without obtaining the consent of the Iron Trades Council, which was necessary under their constitution, the matter had been taken out of the council's hands, and the boiler-makers would have to use their own judgment and act under the direction of the Federated Trades. In a discussion which then took place the opinion prevailed that the federation had not acted wisely in calling out the iron trades, without making provision for giving them financial assistance, and more especially at the time when they had the fight against the Union Iron Works on hand. "For," said one of the delegates, "assessments are levied on all the members working for the support of those on strike, and the more men we have working the larger will be the amount received, and the longer the fight against the Union Works can be carried on."

The Executive Committee was instructed to prepare a review of the situation of the Union Iron Works strike, which should contain a complete statement of the actions of the parties concerned in the strike from the time it occurred up to date. It is also to answer in detail all statements made by the manager on behalf of the Union Iron Works, and to contain new facts, which the council hopes will convince the public of the justness of the action of the iron trades in insisting upon the discharge of certain men.

The Marysville foundry has stopped work for the present.

The cause of the recent boiler-makers' strike

the left eye of Joseph West, causing a painful wound and endangering his sight. Last month his brother Henry, working in the blacksmith shop at the Heslep mine, at Poverty Hill, had one of his eyes injured by a piece of steel flying into it and was absent at San Francisco for treatment at the time Joseph met with his accident. Another brother some time ago was injured the same way at his home in England. There seems to be a fatality in the West family directed to the injury of their eyes by pieces of steel.

S. T. Brown, while at work recently in his mine, near Chas. Lee's place, Butte Valley, Plumas county, was caved on, the bank crushing him to the ground. His son was with him at the time, but was not hurt. He at once set to work to extricate his father, but when he succeeded in getting him out he found that life was already extinct. Mr. Brown was 80 years of age.

THE Pioche Consolidated Company, just incorporated, besides other properties, have acquired the famous Raymond & Ely and Meadow Valley mines, that turned out over \$15,000,000 in bullion in a very short time, and that, too, from a very small portion of the ground above water level. There is also what is known as the black ledge, the ore of which, it is claimed, the new company can work to advantage.

DURING the month of June the bullion shipments of the Navajo amounted to \$51,236.40.

## MECHANICAL PROGRESS.

## Automatic Machinery.

So far as well-built automatic machinery is attended, managed, and overseen by the educated brain and the skilled hand, reproduction may be as nearly reduplication as anything in art can be; but automatic machinery is not necessarily exact machinery. Yet this erroneous belief is not confined to the inexperienced, but is shared, sometimes, by mechanics.

A contractor was seen overhauling the products of some automatic machinery and rejecting more than he approved. Inquiry revealed the fact that out of 500 pieces of the same sort, produced on the same machine, only about 50 passed muster. If ever there were machines which were simply automatic and entirely self-operating, they are the machines for producing machine screws. All the apparent attention they require, as it seems to a shop visitor, is supplying the machine with bars or rods of metal and with oil. The machine is absolute in all its movements—there is no room for variation, except in the dulling of the cutting tools and the inevitable wear of all moving machinery. The machine takes the bar or rod, moves it forward, squares the end, turns the shank up to the head, threads the space between the end and the head, and cuts the screw off the bar, entirely finished, unless it be a screw with a slotted head. And yet these exact machines fail to duplicate absolutely; every day's product must be examined, and it is not uncommon to condemn one fourth of the day's production. The most perfect machinery requires mechanical brains and skill to keep it in operating condition, just as these qualities were required to produce it. There is no intelligence in a machine; it may do rapid work, and when in order may do exact work, but it cannot equal the hand product of human skill, even in some departments of purely mechanical endeavor. A machine-made watch is a good time-piece; but it is not so good a watch as one hand-made; the best machine-made watches require the judgment of the brain and the skill of the hand to make them good. An engraver, with only the tools and appliances that have been the style for centuries, will make, on an average, 1800 cuts or strokes per hour, and produce on 12 different articles a similar pattern conforming to the varying contour of the surfaces. No machine can do this; and if it could, it would have to be guided and controlled by brain and skill. "The thing made is not greater than its maker."—*Exchange.*

## A Boiler Furnace for Refuse Fuel.

MM. Albin & Co., a firm of French mechanical engineers, have made a successful study of the construction of gas generator furnaces for steam boilers, with special reference to the utilization of fuels of poor quality—such as sawdust, tanyard refuse, etc. Their arrangement is described and illustrated in the *Revue Industrielle*, together with a record of tests made under the supervision of M. Walter Meunier, chief engineer of the Alsatian Steam Users' Association. The principles of MM. Albin's system consist in the employment of a tubular cylindrical boiler of considerable diameter in proportion to its length, a spacious steam dome, and an inclined fire-grate supplied with hot air. The fire-grate is stepped with a double tier of horizontal bars placed crosswise of the furnace at a slope of 45°, thus permitting a large volume of air to traverse over and through the combustible. The cold air enters in the first place through flues placed alongside the smoke flues on their way to the chimney, and it is finally led to the front of the double row of bars, which are, of course, closed in from access of fresh air. The whole of the boiler, with the exception of the steam dome, which projects, is inclosed in the setting, and surrounded with flues. The clinking of the fire-bars is managed by a mechanical attachment which rocks them and slices off the clinker.

The charge of raw fuel is in the first place deposited upon a flap door, which can be laid horizontally to receive it; when loaded is turned over, so as to project the charge into the furnace, at the same time closing the opening. Every care is taken to properly ignite the gas before admitting it in direct contact with the boiler plates, and afterward to make the contact as intimate as possible. The apparatus gives most satisfactory results with every kind of green or dry sawdust, and even with tanbark refuse. The stoking is done with great ease, and the clinking does not offer any difficulty. Considering that the furnace only requires charging at most every 20 minutes with the light refuse used as fuel, the labor of attending these boilers is such as the most inefficient workman can furnish, while the fact that the fuel is used without any preliminary drying, even for tanyard refuse, renders the system valuable for isolated factories. The same arrangement burns breeze and dust coal.

HELPS DO MORE WORK.—Machinery is not labor-saving. The man who works with a threshing machine works as hard as his grandfather did with a flail, but he produces greater results. To those who think only of the price of wages, machinery is a fraud, but to the consumer of manufactured articles it is a boon. Our mothers used to card their own wool, spin and weave it and wear it, and it is no disparagement to our wives and sweethearts that they

do not. They can't afford to. If it were not too expensive, the present race of girls and women would do this and more too. Machinery has not obviated the necessity of work, it has only given it a new direction. Good machinery is a good thing, but the man who expects it to do his work will be fooled; it helps him to do more work.

## Hand vs. Machine-Cut Files.

We have several times made brief reference in these columns to the reported relative advantages of hand and machine-cut files. Arrangements are now being made at Sheffield, England, for an extensive trial to determine this question. In the mean time we would refer to a private trial of the same kind made five or six years ago by a large local firm of machinists in England. According to a report of the trial by a correspondent of the *Ironmonger*, although the test was a private one, it was conducted with scrupulous fairness to both systems of cutting, and the workmen and foremen who had the carrying out of the operation were not permitted to know by which process the files which they used were cut. Twelve 12-inch hand bastard safe-edge files were forged and hardened out of the same material by the firm making the experiment. Of these, six were cut by hand on the premises, and six sent out to be cut by the best machines then available. The files were stamped 1 to 12, and six were handed to one foreman and six to another, half of each six being machine-cut. In the case of the first six two trials were made, the only difference between the conditions observed being that, while in the one case the piece of steel operated upon was so fixed in the vise that it projected 3½ inches from the end of the vise; in the other the material was grasped in the middle, with the edge raised above the jaws of the vise.

In every trial the machine-made files proved themselves superior to the hand-made. Much more work, determined by the weight of filings produced, was performed by the machine-cut than by the hand-cut, and in every instance after the hand-cut was pronounced "worn out," the machine-cut competitor was declared to be "moderately good." Acting on the issue of the test, the firm by whom it was conducted have since cut the bulk of their files by machinery. The question is quite an important one to all workers in iron, and we shall look forward with considerable interest to the forthcoming Sheffield trial.

A WASTEFUL ENGINE.—Much loss is frequently met with in setting up engines entirely too small for the work they have. The following, by a correspondent of the *Iron Age*, is to the point:

What do you think of using above \$15 worth of oil on a 20"x24" engine in less than 10 hours? I figured it up, then handed it to the engineer. He said it could not be helped, as with all that oil he had had a hot crank-pin and main bearing all day. So much for putting in an engine too small for the work. On this same engine the crank-pin brasses were perforated with 8" holes about 3" deep, and these were filled with babbitt. It was a nuisance, as every time the pin got hot the babbitt would melt and fill the oil-holes; then there was fun keeping her going until an opportunity arose for disconnecting and boring out the holes again. The amount of oil this engine required was terrifying. Pumping out the pit underneath her was like pumping an oil well. All the bearings had to be kept slushed with oil constantly. The trouble was, the engine had been built to drive a 10" train, and a pair of 16" roughing rolls for making billets from scrap; and as the business increased the billet mill merged into a merchant bar train and a tack plate train was attached to the end of that, so that the engine was unmercifully overburdened.

LUBRICATING GEARS.—Mr. Henthorn, speaking in the *Mechanical Engineer* of greasing gears, says "the only proper way to do the job is to put the grease on with a brush while the wheels revolve slowly, that the working faces of the teeth then receive the lubricant." We have seen millwrights and others greasing gears with a pail while they were in full speed, just pouring the grease on. Why, it just flew off about as fast as it was poured on, and it was not safe to be within a rod of them, as they just raised a centrifugal tempest of grease. Greasing gear wheels in this way does no good, as it is only by the merest chance that the grease gets where it is wanted, to say nothing of the waste. It just drops upon the points of the teeth, and the greater part is immediately thrown off again, and renders everything in the vicinity so filthy that it is disgusting to have anything to do near them. But the most important point of all is that the life of gearing is seriously shortened by such carelessness, as the most accurately-fitting wheels in the world will wear rapidly unless properly lubricated.

INDIA REQUIRING IRON AND STEEL.—The demand of India for iron and steel work is already becoming of considerable importance to the iron industry. There is just now quite a demand for steel bridges and cast iron railway sleepers. One Scotch firm has recently received an order for 1000 tons bridges. The East India office is also calling for large tenders for the supply of cast iron plate sleepers. The demand for iron for that market will soon become quite large, and lead off into a great variety of uses.

## SCIENTIFIC PROGRESS.

## A Solar Cyclone.

Those who have looked through a large telescope under favorable atmospheric conditions at one of those immense cyclones which occasionally break out on the surface of the sun, have derived from what they saw a very good idea of the origin of sunlight. They have seen that the brightest portion of the surface of the sun consists of columns of intensely hot metallic vapors, averaging about 300 miles in diameter, rising from its interior and glowing with extreme brilliancy, from the presence of clouds formed, probably, of shining particles of carbon precipitated from its vapor as the tops of the columns reach the surface and lose heat by expansion and radiation. (A good idea of such a precipitation is had by observing the particles of water condensed from transparent vapor, in unusually high thunderheads, where the action is in some respects similar.) Between these ascending columns are seen descending masses of cooler vapors, rendered dark and smoky by relatively cool and opaque particles of carbon, all or most of the other elements being still maintained by the excessively high temperature in the condition of transparent vapor. In the immediate region, however, where the cyclone is raging, these bright ascending columns are drawn out horizontally by the in-rushing metallic winds (which often reach a velocity of 1000 miles per hour) into long filaments, pointing in general toward the center of the disturbance, which is always occupied by a huge, black cloud of smoke (frequently 20,000 miles in diameter) rapidly settling back into the interior of the sun. Over and across this great central black cloud are often driven long arms of the shining carbon clouds, which, when the cyclonic action is very strong, bend round into slowly changing spiral forms, very suggestive of intense action. A striking illusion, invariably connected with this sight, is that the observer seems to be viewing it from a position quite near the scene of the disturbance, whose minute and complicated details are seen with great distinctness.—*Exchange.*

## The Luminosity of Flames.

The cause of the luminosity of flames has been made the subject of very close investigation. The *Scientific American*, in alluding to the subject, says: "The explanation which accounts for the luminosity of flames of carbonaceous substances, like the candle or coal gas, by the presence of incandescent carbon particles, is, we believe, very generally accepted as correct, although Frankland has endeavored to cast doubt upon its correctness. The facts on which the commonly received explanation of the nature of the light-emitting substance of such flames is based may be concisely presented as follows: 1. The increased luminosity which chlorine imparts to weakly luminous or non-luminous flames, due to its well-known property of separating the carbon as such. 2. A rod held in a luminous flame is smoked only on the lower side—the side opposed to the gas stream; if the carbon were there as vapor, as Frankland assumes, it would be condensed by the cooling action all around the rod. 3. A body held in a luminous flame is smoked even when it is in a state of ignition; this, therefore, cannot be explained on the hypothesis of the condensation of vapor. 4. These carbon particles can actually be seen in the flame when it is made to strike against a second flame, or an ignited surface, when they aggregate to form visible masses. 5. The luminous portion of a flame is not very transparent, no more so than the layer of smoke of the same thickness which rises above a flame fed with turpentine. And, 6th, flames which unquestionably owe their luminosity to the presence of solid particles give a shadow with sunlight, precisely as do hydrocarbon flames; while luminous flames composed of ignited gases and vapors only give in such shadows in sunlight." The views above summarized are the conclusions drawn by Henmann as the results of an extended investigation of the subject, which confirm very satisfactorily the generally accepted theory.

SEEING THE INVISIBLE.—In a recent lecture on the "Solar Corona," by Prof. Wm. Huggins, published in *Popular Science Monthly*, the author says: "We live at the bottom of a deep ocean of air, and therefore every object outside the earth can be seen by us only as it looks when viewed through this great depth of air. Prof. Langley has shown recently that the air mists, colors, distorts, and therefore misleads and cheats us to an extent much greater than was supposed. Langley considers that the light and heat absorbed and scattered by the air and the particles of matter floating in it amount to no less than 40 per cent of the light falling upon it. In consequence of this want of transparency, and the presence of finely divided matter always more or less suspended in it, the air, when the sun shines upon it, becomes itself a source of light. This illuminated aerial ocean necessarily conceals from us, by overpowering them, any sources of light less brilliant than itself, which are in the heavens beyond. From this cause the stars are invisible at mid-day. This illuminated air also conceals from us certain surroundings and appendages of the sun, which become visible on the very rare occasions when the moon, coming between us and

the sun, cuts off the sun's light from the air, where the eclipse is total, and so allows the observer to see the surroundings of the sun through the cone of unilluminated air which is in shadow. It is only when the aerial curtain of light is thus withdrawn that we can become spectators of what is taking place on the stage beyond. The magnificent scene never lasts more than a few minutes, for the moon passes and the curtain of light is again before us. On an average, once in two years this curtain of light is lifted for from three to six minutes. I need not say how difficult it is from these glimpses at long intervals even to guess at the plot of the drama which is being played out about the sun."

SELF-IGNITION OF GREASY COTTON WASTE.—A foreign manufacturer has instituted experiments on the self-ignition of cotton waste, with the following results: A handful of cotton waste was dipped into linseed oil, squeezed out, placed in a wooden box, and the temperature observed by means of a thermometer introduced into the box. The temperature surrounding the box was kept at 76° C. Soon after the temperature in the box rose to 173° C., and smoke issued from the latter. When opened, whereby air was admitted, flames burst out at once. A box, out of which the air was thoroughly excluded, consumed after five or six hours. In another experiment, in which the cotton waste was saturated with rape-seed oil, the box burned after ten hours. With an outdoor temperature of 56° C., Gallipoli olive oil caused the spontaneous combustion of cotton wrapped in paper; castor oil required 24 hours, sperm oil four hours, train oil two hours, for a lively combustion. Considering these results, it will be seen how dangerous it is to let such cotton waste lie around loose—for instance, the waste used for cleaning machinery; and these experiments may throw light on many inexplicable fires.

THE RED SUNSETS.—The discussion as to the cause of the red sunsets for the two or three years past is still continued, and opinion seems to be settling down to the theory that the cause of these phenomena should be found in the atmosphere of the sun rather than in that of the earth. The unusual activity of the sun's atmosphere during the time seems to give much plausibility to this theory. It is held that the violent solar eruptions of the past five years have "so loaded and extended the solar envelope that the nebulosity has become visible from the earth," and of course would be most readily seen just after the sun itself has passed below the horizon. Meantime many scientific men still cling to the explanation of volcanic dust and vapor in our own atmosphere. Sun-spots have had so much to answer for that it would not be strange if we should find much more charged to their account.

INCREASE OF ACCIDENTS FROM LIGHTNING.—Dr. Andries, having calculated that accidents from lightning have increased by from three to five fold during the last 50 years, finds that the causes which have been assigned for the phenomena do not account for all. He regards the main cause as lying in the enormous increase in manufactories, locomotives, etc., which fill the air with smoke, steam and particles of dust of all kinds, while the increased population contribute their share to the impurity of the atmosphere. His own experiments and those of others have shown that all the electrical phenomena of the air increase in intensity with the increase of dust in it.

THE HIGHEST OBSERVATORY IN EUROPE is now being erected on one of the high peaks of the Tyrolean Alps, in the region of eternal snow and about 10,000 feet above the sea level. This observatory is designed more especially for meteorological rather than astronomical observation, although it will undoubtedly be gradually enlarged for usefulness in the latter direction. Should any unusual success attend observations at the Lick observatory on Mt. Hamilton, that fact will undoubtedly attract attention to such a use.

IMPROVEMENT IN BLEACHING.—A new method of bleaching has been discovered, and we understand, a patent applied for, by Henry Nuttall, bleacher, of Fall River Bleachery, by which a saving will be made of over half the coal, labor and chemicals, and three-fourths of the time used by the present system. The new method will make a complete revolution in bleaching. It is said to be ahead of the new style of bleaching done by our English cousins, who use carbolic acid.—*Fall River News.*

LEAD AND PLATINUM.—It is a phenomenon familiar to many, if not all, who have worked in a chemical laboratory, that if lead or even certain of its salts be melted in a platinum crucible the result will be most disastrous so far as the integrity of the crucible is concerned. Directly the lead fuses it alloys with the platinum, and runs through the bottom of the crucible as if it were made of tissue paper.

THE GARTER was first introduced as an ornament and not for use. It was introduced in the sixteenth century, and was at first a most fashionable male ornament. They were worn externally below the knee, and became so expensive and yet so common a luxury that we read of men of mean rank wearing garters and shoe-roses of more than \$20 in value.

## ENGINEERING NOTES.

## A New Method for Utilizing the Water-Power of Niagara.

A large tunnel is to be cut through the rock close by and parallel with the Niagara river, 160 feet below the water above the falls, and running half a mile or more back from the falls. The open end of this tunnel is to empty at the falls a foot or two above the level of the water below the cascade.

Whenever a company wants water-power it may sink a vertical shaft from the surface almost down to this horizontal shaft. In the bottom of this vertical shaft a turbine wheel is to be placed, and below this a smaller shaft, for a tail race, will carry the water from the wheel to the great horizontal shaft, which will then work as a waste pipe to carry off the water. In order to get the needed water to drive the wheel it will only be necessary to build out a short pier on the river shore to catch the edge of the swiftly flowing current and divert a little of it, by means of a ditch or pipe, into the vertical shaft and so past the wheel and through the great subterranean shaft and back into the river again below the falls. These vertical shafts are to be big enough to admit one or two of the workmen, who must place the turbine in position, and afterward attend to it. It is said that a wheel as big as a man's hat will supply 200-horse power.

The plan is to sell the right to sink shafts as close together as practicable along the line of the great waste shaft. It is said that cheap, steady, reliable power is so great an item in manufactures that a committee of Connecticut mill-owners declared it would pay them to remove their mills and factories to Niagara. Freshets, droughts and ice play mischief with those interests that depend on water-power, but no such annoyance, it is said, attends the use of Niagara water. The Niagara never freezes, never overflows and never runs dry. A company with \$3,000,000 capital has been organized in New York City to carry this enterprise through.

**WOODEN WATER WHEELS.**—Wooden turbines have of late been proposed to meet the demand for an excellent and cheap water motor for small powers, and the *Iron Age* thinks there is every reason to believe that within certain limits they will meet with very favorable reception. Turbines, it must be remembered, have the advantage of being small in bulk for their power, and equally efficient for the highest and the lowest falls, and were it not for the fact that they are wholly constructed of metal, their use would probably have long since become more general. Wooden wheels can in some cases be readily procured at a comparatively low price, and as the question of first cost and ease of repairs enters largely into the question of successfully utilizing small water powers for some purposes, and is of greater importance than a high efficiency, turbines have often been unable to compete with wheels of other types. This state of things, it is thought, can be changed by using wood as the structural material, thus securing the advantages of turbines without the drawbacks, and it has been found that in this way their cost can be reduced to about one-fourth of that of iron turbines. In some parts of Europe wheels of this class have been constructed partly of oak and partly of yew, and the results are understood to have been highly satisfactory in every respect.

**CANALS VS. RAILROADS.**—A general but erroneous notion that the day of canals has passed, that they have been superseded by railways, is vigorously combated by Horatio Seymour, Jr., in a pamphlet called "The Canal Age." He shows that railways never have carried freight as cheaply as canals, and probably never can; that the Erie canal, far from being a tax, is a profitable investment for the State; that Germany, Austria, Russia, England and other countries are rapidly extending their canal systems; and that in the extent of our water routes this country is relatively far behind Europe. Thus, France is engaged on four great waterways, for which \$200,000,000 have been appropriated, and which will cost much more; Germany and Russia are constructing a canal from the Baltic to the North sea; England is making canals from London to Liverpool and Bristol, and from Manchester to Liverpool; while Canada is spending \$1,000,000 to improve the Welland canal.

**RAILROAD-BUILDING IN ASIA MINOR.**—The ancient city of Tarsus, where the Apostle Paul was born, has a railroad. British capitalists are constructing a railway in Asia Minor, the first section of which, from Mersina to Tarsus, has just been officially inaugurated. The opening of the road was made the occasion of a grand jubilee, in which the local officials heartily joined. A dozen sheep were sacrificed, there were religious benedictions, speeches, and then a free excursion to the notabilities. Some Arab dignitaries, however, would not trust their lives on the train, saying they would wait till they saw how the extraordinary English contrivance worked.

**COAL VS. WOOD.**—Within little more than a year all the locomotives on the St. Paul & Duluth road (43) have been changed from wood burners to coal burners, though it is almost a continuous forest along the road.

## USEFUL INFORMATION.

## Size of Rooms and Fitting of Carpets.

A correspondent of the *California Architect* called attention, some time since, to the importance of calculating for the sizes of rooms, when building, in accordance with the standard widths of carpets. Says the correspondent: It is easy to cut off or turn under a few inches of carpet, but expensive and bothersome to add that much. Even where a room is one inch too wide for a carpet it is very annoying and expensive. In most cases a moment's thought on the part of the architect would remedy these quite expensive defects. Take a room 4 by 5 yards, an even 20 square yards cover it. But suppose this room 4 yards and 3 inches by 5 yards and 3 inches, and your carpet of a large and showy pattern, from 25 to 30 yards are required. As Brussels carpets are most used and Ingrains are more easily patched, the principal rooms should be made to fit the even sizes of Brussels. You have nice double parlors, and you choose a nice Brussels and find your center widths just 1 or 2 inches too narrow to meet your borders, and even 1 inch compels awkward patching and perhaps from \$20 to \$50 extra expense. This cannot in all cases be avoided, but in the vast majority of cases rooms and halls can be made the right size for carpets, and ought to be. Another point—try to fit a carpet around a door casing with heavy molding, and you have to cut and fold and twist, and then you leave an unsightly, dust-catching corner, as you cannot make the carpet fit neatly around such moldings. Now, Mr. Architect and Carpenter, let a woman give you a very useful lesson: Do not let such moldings touch the floor; leave about a quarter of an inch space and then the carpet can be neatly slipped under them. Nearly all rooms have to be carpeted, not once, but every few years; and carpets have to be put down at least once a year, and many economical housewives have to change the carpets so as to equalize the wear and tear, and the architect or carpenter that compels them to add inch strips and fit around awkward moldings adds 25 per cent to their cost, and is very ignorant of an important practical point in his business.

**A HAIR-CUTTING MACHINE** for the human head is one of the latest reported inventions. The machine is a small box-shaped implement operated with a spring. In operation, after the spring is wound by means of the key, similar to a common clock, if a button is pressed the knife plate reciprocates at a high speed. If the machine is now moved over the head, the comb passes through the hair, which will be cut off by the fixed and reciprocating knife plates a greater or less distance above the comb. Hair can be cut either long or short by adjusting the legs in the box so that the comb and cutters are at the required distance. A person can easily cut his own hair by means of this machine without danger of cutting his ears or injuring the scalp, because the outer ends of the knives are protected by a comb. It is well adapted to clipping sheep, ponies, dogs or hives, thus making a very useful help for farmers, furriers, etc. It has such a universal application for hair clipping, and is said to perform such perfect work, that it is certain to make a very profitable article for a manufacturer's specialty.

**RENEWING FADED INKS.**—A valuable discovery has been made, whereby the faded ink on old parchments may be so restored as to render the writing perfectly legible. The process consists in moistening the paper with water, and then passing over the lines in writing a brush which has been wet in a solution of sulphide of ammonia. The writing will immediately appear quite dark in color, and this color, in the case of parchment, it will preserve. Records which were treated in this way in the Germanic Museum, in Nuremberg, ten years ago, are still in the same condition as immediately after the application of the process. On paper, however, the color gradually fades again, but it may be restored at pleasure by the application of the sulphide. The explanation of the action of this substance is very simple—the iron which enters into the composition of ink is transformed by the reaction into the black sulphide.—*Paper World*.

**TO MAKE INK SPOTS INVISIBLE.**—In order to take away ink spots from paper it is customary to use a blotter, which freely soaks up the liquid, and if by this means all traces of the ink do not disappear, recourse is had to a salt or some substance having the property of bleaching paper, for instance, oxalate of potassium, etc., to attain this end. A simple modification of this renders still better services: Take a thick blotting paper or board, steep it several times in a solution of oxalic acid or oxalate of potassium. Then dry it. If there is a spot to be taken away, apply the blotter which has been prepared in this fashion to the same. In proceeding thus, the ink is entirely removed. The blotter drinks up the ink and whitens the paper at the same time.

**UTILIZING THE MILKWEED.**—We have often wondered, when admiring the silky bolls of the common milkweed, if the material would ever be utilized for manufacturing purposes. Recently a thread has been made from it which is said to have the consistency and tenacity of

imported flax or linen thread. The fiber is long, easily carded, and may be readily adapted to spinning upon an ordinary flax spinner. It has the smoothness and luster of silk, rendering it valuable for sewing machine use. As it grows readily at the North, here may be the beginning of a new industry rivaling that of cotton-growing at the South. Samples of the new material have been introduced into the Boston market.

**USEFUL IF RELIABLE.**—Jerome Prince, of Milford, Mass., is the inventor of an electrical machine for locating articles lost overboard from boats or steamers in deep or shallow water. The model of the machine which Mr. Prince exhibits works perfectly, locating readily iron, steel, gold and silver. The presence of the metal is said to be indicated by rapid revolutions of a compass needle. The machine was given a successful trial at the pond the other day. An iron bar was dropped from a boat and the bottom of the pond in the vicinity dragged with the plummet attached to the machine which was carried in the boat. When the plummet struck the bar it was quickly indicated on the compass. Mr. Prince goes to Boston in a few days to exhibit a model of the machine. He has applied for a patent. The inventor bases his claim on the composition of the plummet and the fact that they will locate gold.

**NEW AND CHEAP EVAPORATOR.**—A member of the Fruit Growers' Association of the United States claims to have invented a cheap evaporator suited to general use, which is far more effective than the more expensive description. The process is complete in from two to three hours. The evaporator is a marvel of simplicity, and can be made by any one at a very trifling cost. By its use millions of dollars can be saved the producer and consumer each year.

**DRY POCKET GLUE** is made of 12 parts of good glue and five parts of sugar. The glue is boiled until it is entirely dissolved; the sugar is then put into the glue, and the mass is evaporated until it hardens on cooling. Lukewarm water melts it very readily, and it is excellent for use in causing paper to adhere firmly, cleanly, and without producing any disagreeable odor.

**FIRE EXTINGUISHERS.**—The ingredients of many of the patent fire extinguishers are said to be 8 pounds carbonate of soda, 4 pounds alum, 3 pounds borax, 1 pound carbonate potash, and 24 pounds silicate of soda solution, which are mixed together; 1½ pounds of this mixture is added to each gallon of water when required for use.

## GOOD HEALTH.

## Doctors Disagree in Regard to What May Be Intrusted to Digestion.

Most authorities are of opinion that cheese is indigestible, yet even on this point doctors cannot agree. A distinguished French chemist has suggested that, to render cheese digestible, a quarter of an ounce of potash should be added to every pound of cheese, while a German chemist has experimented on several kinds, such as cheese, meat, milk and eggs, and he boldly declares that cheese is 'no more indigestible than meat and many other articles of diet.'

Suppers are also usually condemned. Some doctors assert that suppers are not only unnecessary but positively harmful; that sound sleep cannot be obtained after them, and that three meals a day are sufficient. On the other hand, others are of opinion that a light supper is necessary to procure sound sleep. After a meal, they say, blood is drawn toward the stomach to supply the juices needed in digestion. Hence, the brain receives less blood than during fasting, becomes pale, and the powers become dormant. Sleep, therefore, ensues. A doctor says that recently he was called at 2 A. M. to a lady who assured him that she was dying. The body was warm, he says, the heart doing honest work. To her indignation, he ordered buttered bread to be eaten at once. Obeying, the "dying" woman was soon surprised by a return of life and a desire to sleep.

Milk is generally considered a peculiarly nutritive fluid—indeed, a perfect food—and therefore suitable for persons of all ages, when it agrees with their stomachs; yet no less an authority than Sir Henry Thompson states that "for us who have long ago achieved our full growth, and can thrive on solid food, it is altogether superfluous, and mostly mischievous as a drink." He also says that the primary object of drinking is to satisfy thirst, and that water is more powerful to this end when employed free from admixture with any solid material. Chocolate, thick cocoa, or even milk, are therefore not so efficacious in allaying thirst as water. "So plentiful is nutriment," he adds, "that the very last place where we should seek that quality is the drink which accompanies the ordinary meal." In this respect, at any rate, Sir Henry Thompson is at one with the vegetarians.

**IMAGINARY ILLS.**—A Philadelphia physician says that a great deal of what passes for heart disease is only mild dyspepsia, that nervousness commonly is bad temper, and that two-thirds of the so-called malaria is nothing but laziness.

Imagination, he says, is responsible for a multitude of ills, and he gives as an instance the case of a clergyman who after preaching a sermon would take a teaspoonful of sweetened water and doze off like a babe, under the impression that it was a *bona fide* sedative.

**ADVANTAGES OF LOW CEILINGS.**—Rooms with low ceilings, or with ceilings even with the window-tops, says the *Popular Science Monthly*, are more readily and completely ventilated than those with high ceilings. The leakage of air which is always going on keeps all parts of the air in motion in such rooms; whereas, if the ceiling is higher, only the lower part of the air is moved, and an inverted lake of foul and hot air is left floating in the space above the window-tops. To have the currents of fresh air circulating only in the lower parts of the room, while the upper portion of the air is left unaffected, is really the worst way of ventilating, for the stagnant atmospheric lake under the ceiling—although motionless—keeps actively at work under the law of the diffusion of gases, fouling the fresh currents circulating beneath it. With low ceilings and high windows no such accumulation of air is possible, for the whole height of the room is swept by the currents as the dust of the floor is swept with a broom. Low ceilings have also the advantage of enabling the rooms to be warmed with less expenditure of heat and less cost for fuel. The above does not agree with the generally accepted idea of the height of rooms in dwellings, but the authority is good and well worthy of consideration by persons about to build.

**ICED DRINKS IN DYSPEPSIA.**—And now a few words as to the beverages to be taken. Americans are a dyspeptic people; they drink much iced water at meals; *ergo*, iced drinks at meal-times are bad. They may be when carried to excess; this is not denied. But iced drinks are not the cause of the widespread dyspepsia in the United States. There are other potent factors in action. Iced drinks are very grateful to the thirsty, but too much indulgence therein produces a torturing thirst, as the person who indulges in eating snow in the Arctic regions discovers quickly. Just as snowballing causes the hands first to feel cold and then to glow with heat if continued, so the constant application of an iced fluid to the fauces, at first grateful, become a source of intense discomfort; for the blood-vessels are first contracted and ultimately paralyzed, and then the fauces glow with warm blood, like the skin of the snow-baller's hands. Iced fluids are not desirable for dyspeptics, to say the least of it. Ordinarily at dinner the ice pudding is followed by a glass of liquor—"to correct it." A certain temperature is requisite for digestion, and too much cold is undesirable.—*From Dr. J. M. Fothergill's "Indigestion and Biliousness."*

**THE POISON OF THE SCORPION.**—Apparently no very complete exhaustive analyses of the poison of the scorpion have yet been made. The best on record are those by Jousset, presented to the French Academy in 1870 and published in the *Comptes Rendus* of that year. He gives no definite statement of the chemical constitution of the venom, but does state the mode of its action upon the blood, by which in severe cases it causes death. It affects the red corpuscles, paralyzing them so that they cohere one to another, thus becoming agglutinated until they are unable to pass through the capillaries, and may cause fatal obstruction. So far as known, there is no chemical antidote which can neutralize the poison, but inasmuch as, like all animal poisons, the action on the nerve force, or in other words, the vital force, is in the nature of depression, a remedy which stimulates that force temporarily is plainly indicated. Alcohol is always available for that purpose, and being easily obtained, is perhaps more serviceable than any other. Bromide of potassium is of high value, but can be used safely only by the physician himself.

**COFFEE** acts upon the brain as a stimulant, inciting it to increased activity and producing sleeplessness; hence it is of great value as an antidote to narcotic poisons. It is also supposed to prevent too rapid waste in the tissues of the body, and in that way enables it to support life on less food. These effects are due to the volatile oil, and also to a peculiar crystallizable nitrogenous principle termed caffeine. The leaves of the plant likewise contain the same principle, and the inhabitants of the island of Sumatra prefer an infusion of the leaves to that of the berries. Its essential qualities are also greatly changed, the heat causing the development of the volatile oil and peculiar acid to which the aroma and flavor are due.—*Ag. Reporter*.

**INSANITY IN CHINA.**—With a population of about 300,000,000, China has not a single insane asylum. Is this indicative of freedom from insanity in China or of the proverbial indifference of that race to the sufferings of its individuals? In this State we believe that the proportion of insane among the Chinese is nearly as great as among other nationalities.

**COMPULSORY REVACCINATION** of the soldiers was established by the German Government 11 years ago, and since then not a single death from smallpox has occurred in the German army.

**DOCTORS IN CHINA** charge 5 to 10 cents a visit, and are said to be kept exceedingly busy,

## MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

## CALIFORNIA.

## Amador.

**MINING ACTIVITY AT MIDDLE BAR.**—Amador *Dispatch*, July 17: Last Saturday the parties who over a month ago bonded the Marlette mine at Middle Bar from A. J. Sargent, sent a check on New York for \$2000—the first payment on this contract, which was to be paid in 60 days, the balance (\$25,000) to be paid in six months, for this mine, which is near the town of Middle Bar on the Mokelumne river, and instead of paying the \$2000 in 60 days, they have paid it in 35 days. Mr. Petre himself will be here and commence active operations on the mine forthwith. In fact, Mr. Sargent has already ordered the timbers and set men to work cleaning out the shaft. Mr. Petre is an old Lake Superior miner with an abundance of means at his command to open up and develop this mine, and will this season put up a 20 if not a 30 or 40-stamp mill on or near the mine. Thus, at last, the boom for Middle Bar has begun in good earnest and on a grand scale. This work, we understand, is to be followed by the erection, in the near future, of a ten-stamp mill just above the bar on a mine now owned and being worked by Col. Robinson, who has already built a comfortable house near his mine and moved his family into it. He has found at 40 feet a five-foot body of solid quartz of good paying rock. This mine is on the Zeile ledge of Jackson, and will, in all probability, equal this old Zeile mine in richness, which is one among the best and heaviest mines in the State. Mr. James Farrell and his Stockton partners will this week commence operations on their mine, which is the second mine south of this Marlette mine that Mr. Petre has bought and is now working. Thus it will be seen that no less than three different quartz mines at Middle Bar will be in active operation this summer, besides the Neville or "Mammoth" mine at that place, which will put a mill, smelter and sulphurets works at the Bar, making no less than four gold quartz mines and mills that will be in active operations here, thus making this mineral belt of gold quartz leads in the southern end of "Little Amador" equal to the northern end at Plymouth, where the Consolidated Plymouth mines and mills are located. Then add to this the Kennedy mine's 40-stamp mill that is already under way, and with the old Zeile, the Moore and the Amador Queen mines and their separate mills all at work, and we have some eight mines and mills at work within a distance of four miles from Jackson, and making this the center of trade and supplies. We must also state that Abe McKinney has bought an iron whim which he is putting up at his mine, and will sink the shaft 100 feet deep. This mine joins the Marlette mine at Middle Bar, and is one of the richest quartz mines there.

**WORK COMMENCED.**—Amador *Ledger*, July 17: Work was commenced on the Marlette claim at Middle Bar last Monday. This claim, together with the Sargent mine adjoining, was recently bonded to W. Petre, an Eastern capitalist, for the sum of \$28,000. The work at present consists in cleaning out the tunnel. It is expected that the grading for the millsite at the Kennedy will be completed this week. The value of the last cleanup at the Volcano Gold Gravel Mining Co.'s claim at Volcano, commonly known as the big tunnel, is variously estimated at from \$12,000 to \$15,000. It is expected that the Zeile mill will be started to its full capacity of 40 stamps about the 1st of next month. George W. Horn is prospecting a quartz claim a few hundred yards south of the Kennedy, west of the main road. The quartz is very much broken up and nothing can be said of the prospect as yet. W. Boxall, who has been driving a prospect tunnel into Mattley's hill, a quarter of a mile west of Jackson, is in over 200 feet. He has done the work himself, with the help of two sons. He is drifting to strike a ledge which he believes to run in that vicinity, and expects to have to go 200 or 300 feet further before he reaches quartz.

**SUTTER CREEK.**—The news from the mines of this vicinity is of a discouraging character. A telegram was received from San Francisco last evening ordering work to be suspended at the Amador Consolidated. Whether this means a temporary or permanent shutting down of the mine is not known. The work of keeping the water out continues. As the company have lately been at great expense in getting a new air compressor and also a new rope, it is hardly conceivable that the intention is to abandon prospecting altogether. It means some important change in the program, but whether for better or worse remains to be seen. The new ten-stamp mill at the Iowa will be completed in about a week, when the crushing of surface rock will be commenced. The building of ten additional stamps at the South Spring Hill mine has been commenced. It will take six weeks to complete the job. H. G. Murray, who has been in Calaveras county for several weeks past, has returned and will take charge of the South Spring Hill job. At the Lincoln a break in the main water pipe has brought the machinery to a standstill for about a week.

## Butte.

**BUTTE CREEK.**—*Record*, July 17: Mr. Hedges and Ira Wetherby are out on a prospecting trip high up in the hills. They have a full outfit for the summer's trip. They are experts at mining, and men of large experience, and know the feelings of one who has picked up nuggets, the largest of which weighed 52 pounds. They are men of energy and perseverance, and I know no obstacles they cannot surmount.

**HELLTOWN MINES.**—Messrs. Howley & Gale, who have recently opened a mining claim near Helltown, are doing very well—much better than they anticipated. They have a good and lasting claim; from information and observation they are satisfied. Uncle Joe Rice is again turning boulders from the bottom of the creek, and has a good showing for a good summer's work. Wm. Longley and Harry Moore are his partners. The Hintz mine is doing better, as they drive their tunnel into the flat. They are taking out coarser gold and more of it.

## Calaveras.

**MINING SALES.**—Calaveras *Chronicle*, July 17: The Marlette mine of Middle Bar, owned by Mrs. Julia Sargent, has been bonded to Mr. R. W. Petre of Duluth, Minnesota, and the work of cleaning out the tunnel has been commenced by Jack Sargent, under advice from Mr. Petre, who is expected here shortly from Duluth with money to push the work of development with all possible dispatch. The conditions of the bond were \$2000, 60 days, which payment has already been made; \$3000, six months, and \$20,000, one year. The mine to be worked and hoisting works and mill erected suitable for the reduction and concentration of the ores. The gross profits of the mine applies on the preferred payment. Col. Robinson, who negotiated the bond, receives a commission of 10 per cent of the sale money. The Marlette has a U. S. patent for title, and is upon the Nevill or west lode of the mother belt, and contains 1500 by 600 feet. The "Little Sargent" ground adjoining, and upon the same vein, containing 170 feet, no patent, was placed to the same party with bond for \$3000, payment in six months. Within the last five days the sale of the St. Julian mine of 1400 feet, located between the "Little Sargent" and Nevill mine, was negotiated by the same party to Mr. Wm. M. Curtis for the controlling interest, 62,500 shares, at about 10 cents per share; 10 per cent down in 45 days; 10 per cent in six months, balance, one year. The same rate paid for the control will be paid for the rest of the stock should the parties desire to sell. Col. Robinson is sinking on his Middle Bar mine at Middle Bar, and will likely consummate a sale soon to San Francisco capitalists for one-half interest for mill and hoisting works. The ore assays \$20 per ton.

## Inyo.

**DARWIN.**—Inyo Co. *Independent*, July 16: Everything indicates that lively times are about to set in at Darwin. Men are wanted at the Defiance mine, and Mr. J. S. Gorman is opening up several claims that will each employ a number of men. At other mines work no doubt be begun that will swell the number of men employed and help the general prosperity.

**PALMETTO.**—*Register*, July 15: The indications are that the Palmetto Company is going systematically to work to develop the series of mines owned by the company in Palmetto district, which is situated about half way between Piper's Ranch and Lida Valley. Some 15 or 20 years ago the company had a fine mill there, and ran it for a short time; but troubles of some sort arose and operations ceased, since which time the entire mill has been carried off by different persons. The mines—some five or six in number—were then secured by U. S. patents, and therefore remain to the company. It has always been asserted by those knowing something of the facts that the ore yielded well by mill process, and it is the common belief that they are really very valuable. Work on a small scale has been going on there for several months, but now additional men are being put on, and no doubt is entertained but that something more than mere prospecting is on the tapis.

**LEAD CANYON.**—Erwin & Fuller are still hammering away on their mines in Lead Canyon, which is situated between Waucoaba and Saline valley on the eastern slope of the Inyos opposite Independence. They make an occasional shipment of ore by which to keep up expenses, though the main object is to show up something that will justify the erection of works near by, for which there are the finest facilities—wood and water-power. The prospects of making such a showing of lead ores are considered very good indeed. It is said to be the best fluxing ore ever put through the Elva furnace, and to run high in silver, although we do not now remember the figures. There are a number of these lead prospects in the vicinity, and also in the adjacent districts, where also are found some very promising silver ledges. The chances are that there will be a prosperous camp over there some of these days.

## Mono.

**BENTON ITEMS.**—Inyo *Register*, July 15: Miller's mill is running along steadily. The chlorides on the hill and up in Montgomery canyon are doing fairly well. Tucker & Mitchell shipped two tons of silver-lead ore on Tuesday. M. Harrington is taking out some good ore again. P. Dowd, Joe McDermott, and several other persistent prospectors have been making a few developments on some of the gold ledges of Clover Patch and in the vicinity of the Wild Rose.

**THE STANDARD CON.**—Bodie *Miner*, July 19: Number of men employed in and about the mine: Engineers, 2; pumpman, 1; shiftbosses, 1; carpenter, 1; blacksmith, 1; miners, 23; stationmen, 4; carmen, 5; timbermen, 1; laborer, 1; total employed, 40. Drifts and stopes without special change. Ore shipped to mill for week, 288 tons. Standard side of Bulwer mill running steadily.

**THE MONO.**—The south drift on 700-foot level is extended 24 feet. The east crosscut from south drift on 700-foot level is extended 14 feet. The north drift from east crosscut on 700-foot level is extended six feet. The east crosscut from south drift on 550-level is extended 10 feet.

**THE CON. PACIFIC.**—In drift north on the Fortuna vein has been advanced eight feet. Vein looking about as at last report. During the past week we have had bad air to contend with in the winze down from the 135-foot level. Have advanced the work five feet with no change in vein to report.

**THE BODIE.**—The upraise above 400 is extended 24 feet. The north drift 700 is extended five feet.

## Nevada.

**GOOD ORE.**—*Tidings*, July 16: Some extra rich rock was struck last night in the Boston mine, which was formerly known as the Granite Hill. The Boston is down to a depth of about 300 feet, with a ledge averaging about 18 inches in thickness. The general average of the ore is very good, while that found last night was a bonanza, almost. The last ore crushed from the Boston mine yielded over \$80 per load, and was cleaned up at Rodgers' mill several weeks since.

**QUARTZ.**—*Transcript*, July 18: John Curry recently discovered quite a rich pocket of quartz while prospecting on Rush creek, a couple of miles west of town. He has already taken out about \$400 and thinks there is more left.

**A PRODUCTIVE MINE.**—The Nevada City mine

not only continues to hold its own, but improves with each day's work done. Incline No. 1 is down 850 feet. The ledge in the lower level shows six feet of milling ore carrying good quantities of free gold. The north drift is richer than the south one, but they are both good enough. Shaft No. 2, about 1200 feet north of No. 1, is down 530 feet to the drain tunnel with which it was connected last month by an upraise. Levels are being run each way about 100 feet above the tunnel, and the ore deposits are of most gratifying extent and quality. Superintendent Sprague, when in San Francisco recently, purchased 2000 feet of steel rails for the car track in the tunnel, so that all the ore from the mine can be conveyed with cheapness and rapidity to the mill which is at the old incline. This mill has 20 stamps and although being run night and day it is not capable of crushing the ore as fast as it can be taken out. It is quite likely that more stamps will be added to the mill during the coming fall. There are about 60 men employed by the company, and there will be additions made to the force as new ground is opened up. There is enough ore now developed to keep the mine in operation many years to come. There is a big quantity of ground in the claim that has not yet been penetrated, but it is morally certain to be very productive when the company get into it.

## Placer.

**A CARLOAD.**—Placer *Republican*, July 17: One often reads that a mine averages a certain amount of gold to the carload. This is rather indefinite, because the cars used in different mines vary in size, and the quartz or gravel may be coarse or fine; but in general a carload may be taken to mean about a ton. The cars in quartz mines are generally a little smaller than those used in gravel mines. In the Hidden Treasure mine there are between 40 and 50 cars used to haul the gravel. These are a trifle smaller than the average car in drift mines, but their dimensions will sufficiently indicate the size generally in use. They are (inside measurement) 57 inches long, 27 inches wide and 21½ inches deep. They therefore contain 33,088 cubic inches, or a little more than 19 cubic feet. A cubic foot of gravel weighs about 110 pounds, so that one of these cars will hold about a ton when even full, and a carload may be taken to mean a ton.

**HIDDEN TREASURE.**—The upraise in the Hidden Treasure mine at Sunny South has progressed 250 feet, which leaves about 600 feet before the surface is reached. For some distance the work has been done through cemented sand, which was very hard to remove and was found to solidify in a very short time. This material was used to ballast the road in the tunnel. Last week the workmen got through the cement into a body of gravel, from which the water ran down into the mine in such volumes as to cause some delay and make mounting into the shaft very difficult. However, progress is being made as fast as the owners expected.

**WORK RESUMED.**—Work has been resumed in the old Gold Blossom mine at Ophir, under a new management. The ten-stamp mill has been put in perfect order and the water is being taken out of the old shaft. A new shaft is sinking on the Marion ledge near its junction with the old ledge. The two ledges run along side by side, so that short crosscuts will reach both. Dr. Wright has charge of the mine.

**A NEW MINE.**—*Herald*, July 17: A new ledge is being developed on ground belonging partly to Rhodes and partly to McCurdy, a little south of the Auburn and Lincoln road, and about a mile west of Ophir. The shaft is now down about 80 feet, and at that depth there is a two-foot vein of good milling ore. It is owned by a company of six individuals, viz: The old gentleman Rhodes and his three sons, J. F. McCurdy and E. L. Dodge, the latter of Oakland. They have christened their enterprise the New Year's Mill and Mining Co. They are now putting up a five-stamp mill to be run with an overshot wheel by water power, and to cost about \$5000. The mill building is completed and the machinery is being put in place. With a mill of their own to crush the ore, the company is confident their mine will prove a paying and valuable property.

## Plumas.

**GRANITE BASIN.**—Cor. Plumas *National*, July 15: The Basin is on a boom this season. Mr. J. A. Hall has got the lease extended on the Morning Star mine, has bought the Jenny Lind mine, and is negotiating with Messrs Sparks & Parker for the Caldwell mine. He is working about half Chinese. Mr. Christie comes next in order. He is stoping in his lower tunnel, and has rock that will go \$500 per ton to encourage him for the long tunnel he has to run. Rockefeller & Co. are running their mill to its full capacity. They intend to put in an overshot water wheel in place of the hurdle, as they intend to put in concentrators and pans, therefore will need more power. Mr. Johnson is running his mill steady on the best of ore. He has gone below to make arrangements for improved machinery for his mill. He informs me that he has not been saving more than half of the gold in the rock.

## San Bernardino.

**PROVIDENCE.**—Cor. Calico *Print*, July 18: The Bonanza King Co. is now working about 20 miners in opening up its mine. The lower levels are said to be looking as good as at any time since the opening of the mine. The grade of ore on the eighth level being as good as on the surface, 300 to 400 ounces is not an unusual assay. This speaks well for the mine at that depth. The Bonanza King would put on a few more good miners at the present time. A new rich discovery was made about two months ago by two prospectors by the names of Witts and Slidel. They have already made a sample shipment to Kingman of five tons, the average being over \$150 per ton. The ore shipped was gold, carrying about 40 ounces of silver. There appears to be three strata in the ledge, which is situated about west from the Bonanza King, on the west side of Providence mountain. There is a small gold vein, a silver and gold vein and a large body of carbonate carrying about 30 to 40 ounces of silver and some gold. Those who have examined the prospect speak of a likelihood of another bonanza. The owners are now preparing to sink and see what they have got.

**RUMORED SALE OF THE PERSEVERANCE MINE.**—It is generally understood here that Mr. Kerr's

group of mines north of the Bonanza King's property has been bargained for, and ere this is in type that we are likely to have another company in Providence. The party negotiating is your townsman, Mr. Bahten.

**A NEW FIVE-STAMP MILL.**—Thirty-five miles north of here is a mining camp called Mescal. Messrs. McFarlane & Barrett, the lucky owners of the Cambria mine, some time since bonded their claim to Los Angeles parties. Developments have steadily since gone on, so that they now claim to have enough ore in sight to run a five-stamp mill for three years without doing any more developments. The company, under Mr. Barrett's immediate supervision, is now grading for a five-stamp mill; part of the lumber is already on the ground and the mill will be hauled as fast as John Domingue's big freight teams can bring it in. They have struck a splendid supply of water not more than a mile from their mine, giving them undoubtedly sufficient water for their mill. The mine is opened with two tunnels on the ledge, so that they now have 200 feet of back stoping ground some 200 to 300 feet in length. The mill is under the superintendency of L. W. Carr, of Los Angeles, and is expected to drop its stamps about the 15th of September.

## San Diego.

**JULIAN.**—National City *Record*, July 16: The mining news from the Julian district is encouraging. The Shenandoah mine is showing up new discoveries and richer ledge matter; the Owens is coming to the front with an improved record. The City of Richmond is making extensive preparations for work with good pay ore at a depth of 80 feet, and the Keystone mine is also turning out rich quartz.

## Shasta.

**MILL STARTED.**—Shasta *Democrat*, July 14: Tom Green's new five-stamp quartz mill was started up last Wednesday, and it runs like a top. The Windy Camp Mining Company have commenced new development work on the Ballaklala mine. The brick for the furnace and some of the machinery of the reduction works for the Scheerer mine is now on the ground, and the erection of the plant will commence this week. It is reported here and at Shasta that operations will be resumed at Iron Mountain in a few days. The report is based on a telegram received a few days ago by the man in charge to have everything ready for a force of men to be put to work. The Whitton & Spellman claim, on the east side of the divide, between the White Bear and Ellis claims, Squaw creek, shows about five feet wide and prospects fairly. The owners intend to sink 50 feet on it during this season. This claim is thought to be the first extension east on the Lillian Maud.

## Siskiyou.

**SCOTT BAR.**—Yreka *Union*, July 17: Bennett & Co. are all pumped out and have started to work in the gravel. The Quartz hill miners are still working, it being very seldom that they get such a good year for water, but the water begins to get pretty slack. Ed. Reynolds & Co., who have laid off a week for rest, will resume operations in their claim on Skunk hill. Mr. Reynolds has made a good run of it this year.

## Sierra.

**THAT NUGGET.**—*Tribune*, July 16: The \$7000 gold-nugget which was found in Hayes & Steelman's drift-claim was exhibited to our citizens at A. W. Crowell's store last Saturday afternoon. The sight was good for sore eyes. One old '49er said he had rather own that nugget than any jewel in England's crown. You bet, it was enough to make the "old boys'" eyes sparkle, as well as the young ones'. A fortune could, doubtless, be made by exhibiting that chunk of "yaller stuff" in the cities and charging those who would wish to see it ten cents apiece. We understand that Messrs. Hayes & Steelman will make an unusually large cleanup of amalgam this season, which, together with the nugget, will place them in very comfortable circumstances. These young men located this claim themselves after several others had prospected it a little and then abandoned it.

**THE HORSESHOE MINE.**—The owners of the Horseshoe quartz claim, who reside at Downieville, are considerably elated over recent discoveries made at their mine. Judge Vanciel last week paid Sid York \$850 for the latter's interest in the property. The vein shows some very rich ore in the croppings, and gives every promise of permanency. This claim is located in Gold Valley. The company was incorporated a few weeks since.

**BALD MOUNTAIN.**—*Mountain Messenger*, July 17: Only eight men are now working underground, and 15 in the creek for the Bald Mountain Company, whose energetic and public-spirited stockholders deserve to be pensioned for the steady work at good wages afforded by them to hundreds of worthy men, and the millions of gold during the past 12 years poured from their mine into the treasury of the world; and the northeast extension of the main lead of the Bald Mountain in course of development up the ridge on the Extension ground promises to fully equal, and perhaps distance, its brilliant predecessor. The new main tunnel of the South Fork Company is in 850 feet. A contract for 800 feet and an airway for 500 feet has been let to D. Finane, at \$5 a foot for the tunnel and \$1.50 per foot for the airway. They are running toward an old claim of E. A. Melley, which he has been unable heretofore to develop for lack of drainage, and beyond to their deep channel, for which, it is believed, they are sufficiently low. The Pennsylvania Company are preparing to start a tunnel to tap their pay channel near the Cornish ranch. The Arizona Company have let a contract for 250 sets of timbers and 5000 spiling, and are pushing their upper tunnel ahead and expect good pay ground in the near future.

**PROSPECT.**—A very fine prospect has been obtained in the Horseshoe ledge, situated on the ridge between Salmon and Gold lakes. The ledge was located years ago by Enoch Andrews and Dr. Jump, and some prospecting was done. Recently it was relocated by Wehe, Ford, S. York and others and incorporated. A couple of men were put to work on it last week, and in a few days they exposed the ledge and took rock rich in free gold. Several persons here have invested quite heavily in the stock since the strike. The ledge is about three feet wide, and the general character of the quartz has been pronounced excellent by experts,

Judge Van Clief has put Jerome and Wm. York at work at the old Slug Canyon quartz claim. The tunnel will be reopened, timbered, and the incline cleaned out, and the ledge sunk on to some depth below where it was formerly developed. The mine showed very good ore when it was formerly prospected.

#### Trinity.

NEW RIVER.—Humboldt Standard, July 17: Mr. Dungan says considerable bullion is now finding its way out from the New River mines. The output of the precious metal is steadily increasing. Between 80 and 90 men are now working in the mines, and it is confidently believed at least 300 will be profitably employed on New River before this time next year. Placer mines on the Trinity have yielded better this season than for many years—very much better than during last year.

#### NEVADA.

##### Washoe District.

CON. CALIFORNIA AND VIRGINIA.—Enterprise, July 15: The average daily yield during the week has been a little short of the regular 400 tons and the average assays, from mill samples, about \$11 per ton. On the 1500 level, the northwest drift from the C. and C. shaft toward the Ophir ground is in 400 feet, making rapid advancement in good working ground. The shaft station on the 1500 level is being repaired, and put in complete order for a drift to the northward or northwest. On the 1560 level the southwest drift is now in about 205 feet. Material, vein matter considerably mixed with porphyry and low-grade ore.

BEST AND BELCHER.—The hauling of the requisite stone for the water bulkhead on the lower level, to shut out the strong flow of water coming from that direction, commenced yesterday. It is to be made a model of strength and perfect efficiency. The water is easily held at a point 12 feet below the track floor of the station and level. The repairs and requisite retimbering are being well advanced. The boiler capacity of the hoisting engines being found to be insufficient, a pair of first-class ones have been recently procured from the Omega mill, and will be placed in position shortly.

CHOLLAR.—The north lateral drift on the 3200 level is now in 83 feet from the Combination shaft station. The first 30 feet was driven in a north-westerly direction, subsequent to which the course of the drift was changed to due north. It is skirting along the easterly borders of the ore vein recently developed, and the distance between this drift or shaft station and the Hale and Norcross line being only 60 feet this drift is apparently now in Norcross ground. A lateral drift south from this station has been commenced, which is now out 20 feet. This is intended to develop the Chollar ground in that direction, following along the east side of the vein. Work is to be resumed forthwith in the west face of the station to develop the very promising and important ore vein recently struck at that point.

SAVAGE.—On the 600 level the drain boxes are about all in, and the requisite retimbering and similar work found necessary by the badly swelling ground passed through by the main south lateral drift is completed. The advancement of this drift into the good body of ore found in its face will be next in order. The east crosscut shows only vein matter with little quartz in its face.

HALE AND NORCROSS.—Work has been resumed in the south lateral drift on the 3200 level from the bottom of the deep winze in order to assist in making the desired connection with the Combination shaft as soon as possible. The north lateral drift toward the Savage from the deep winze station on this level is now out 93 feet, 34 feet having been added during the week. Material, vein porphyry, quartz and clay. On the 2900 level the west crosscut from the main north lateral drift shows no particular change in material—vein matter with bunches and streaks of good ore.

GOULD AND CURRY.—On the 500 level the west crosscut has been advanced 18 feet and a south lateral drift started from it is now in 12 feet. On the 550 level at the top of the upraise incline the west crosscut has been extended 25 feet and its course changed to the north, making it now north lateral drift No. 2. North lateral drift No. 1 on this level has been extended 10 feet, making a total of 59 feet. All these drifts mentioned are merely in promising vein matter.

MONTE CRISTO.—The main drift west on the 150 level from the new shaft still progresses, and is in hard porphyry and other vein matter, having about 60 feet further to go to get into the main ore vein itself, striking it about 100 feet below the deepest workings.

OPHIR.—The rumored strike of good ore in this mine is officially denied. The south drift on the 1200 level is merely in a vein porphyry formation, and on the 300 level the crosscut west develops nothing of importance.

SIERRA NEVADA.—On the 520 level the north lateral drift, No. 2, from the west crosscut has been advanced 49 feet, making a total of 300 feet. Material, porphyry, clay, and poor, decomposed quartz.

POTOSI.—Chambering out for a header for diamond drill hole No. 6 east, near the Chollar line, and the reaming out of drill hole No. 5, constitute the advancement of work during the week.

ALTA.—On the 700 level the west crosscut has about 60 feet further to go to intersect its objective point, the old Keystone ledge.

YELLOW JACKET.—About 140 tons per day continues to be the regular yield from the old ore stopes and breasts above the 1500 level.

CROWN POINT AND BELCHER.—Daily yield, 400 tons, and work going ahead vigorously as usual in all the old ore stopes and breasts.

KENTUCK.—Daily yield, 40 tons of low-grade from the old workings above the 1300 level.

#### Aurora District.

ESMERALDA CON.—Walker Lake Bulletin, July 15: The late-appointed officers of the Esmeralda Consolidated, limited, are Mr. Colcord, superintendent, and Mr. Parr, formerly of Bodie, assistant superintendent. The company's mill is constantly at work on one of the upper levels of the Humboldt, and it is said that work will be renewed in sinking the shaft deeper. Mr. Ann, one of the

London directors, will remain here for some time. Negotiations are pending for work upon the Antelope mine. It is also reported that the control of the Silver Lining mine has changed hands in San Francisco and active operations will soon be commenced upon it.

ANTELOPE.—Walker Lake Bulletin, July 21: The owners of the Antelope, Judge McKinstry, of San Francisco, and Judge Seawell and L. H. Newton, of Aurora, have let a contract to run a large drift from the main tunnel, which is 1000 feet long. This drift will run through unexplored ground and will strike the lode much deeper than it has hitherto been worked. The ore taken out in former years was very rich and extensive, and the result of this drift is anxiously awaited.

#### Eureka District.

ORE SHIPMENTS.—Sentinel, July 17: During the past week ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Richmond works—Macon City mine, 1½ tons; Silver Plate, 2; Antelope, 16; Lincoln, 4; Bertrand, 2½; Western Contact, 2½; Tybo, 7; Kentucky, 2; Hamburg, 70; Geddes and Bertrand, 10; Mt. Hope, 12. To the Eureka Con. works—Murray mine, 3 tons; Dunderberg, 43; Williams, 40; Summit, 5; Bailey, 1½; Scott, 1½; Pentier, 5; Woodchopper, 4.

A NEW DOUBLE-COMPARTMENT SHAFT.—Eureka Sentinel, July 17: Superintendent McAulay, of the Bowman mine on Adams Hill, informed a Sentinel reporter last evening that he will shortly commence the sinking of a new double-compartment shaft on what is known as the Europa ground, some 600 feet distant from the old shaft. The company has great confidence in its property, and mean to prosecute exploration work systematically and energetically.

#### Jackrabbit District.

IMPROVING.—Pioche Record, July 14: The Onandago mine, at Jackrabbit, continues to gradually improve; every week's work enhances its value. It is pretty certain now that the ore goes down, and that it improves in silver as depth is attained, is satisfactorily demonstrated. The ore from this claim goes such a high percentage in lead that in Salt Lake City it will bring "more than it is worth." A shipment of a couple of carloads of ore from this mine will soon be made.

#### Moss District.

RICH ORE.—Pioche Record, July 14: The Montreal mine, in Moss district, Esmeralda county, is showing a vein of very rich ore, on which the mill will begin running in a few days.

#### Pine Grove District.

PROSPECTS.—Lyon Co. Times, July 15: The prospects for Pine Grove are now said to look more favorable than ever before. From now to the first of August it is estimated that \$20,000 worth of bullion will be shipped from the camp. The mill started last Tuesday on gold rock from the Wilson mine that will work from \$40 to \$50 per ton. Five contracts have been let in this mine and about 15 men are at work in the camp. Mark Erway, of Greenfield, now runs a stage to Pine Grove carrying the mail twice a week, Tuesdays and Fridays.

#### Pioche District.

LEAD ORE.—Pioche Record, July 14: Lead ore is all the go here now with chlorides. Silver appears to be only a secondary consideration with them. Ore going 40 per cent lead and \$50 silver is a more desirable article than \$125 chloride ore. Lead ores shipped to Salt Lake go like hot cakes and bring big prices. It is what the smelters need.

#### Railroad District.

BULLION AND COPPER MATTE.—Elko Independent, July 15: Stoker's teams brought in from the furnace at Railroad district, Sunday evening, 20,700 pounds of copper matte which was shipped yesterday by Warner & Co. to St. Louis. Warner & Co., also from the same source, received 53 bars of bullion, weighing 5270 pounds. They also received from the Tripoli mine, now the property of J. Henderson, 42 sacks—5900 pounds—of ore of high grade. The bullion will be forwarded to the Selby Smelting Works at San Francisco.

#### Wild Rose District.

WILL HAUL THEIR OWN ORE.—Silver State, July 15: Supt. McCurdy has bought the teams, wagons, etc., of T. C. Emery, which have been engaged for over a year past in hauling concentrated ore from the Paradise Valley mill to this town. He has also purchased a Tuscarora team, making in all about 30 animals and six or eight wagons, and the company will henceforth do their own hauling, bringing ore here and taking supplies to the mill and mine.

ORE SHIPMENTS.—Last evening E. Reinhart & Co. shipped 20,165 pounds of ore and 27,190 pounds of concentrations from the Paradise Valley Co.'s mines to Argo, Colorado. One of T. C. Emery's teams arrived yesterday with 16,070 pounds of concentrated ore from the Paradise Valley Reduction Works.

#### ARIZONA.

HUMBURG.—Prescott Courier, July 15: Messrs. Champie and Dodge reached Prescott yesterday from the mineral region south of Prescott. They went as far as Humburg district, where more than 100 men are engaged in mining. They found the Basin mill idle for want of water. Dawes, they say, is still pumping water out of the Peck. Mr. Jacobs, of Hassayampa creek, came in yesterday with a big lot of placer gold which he sold to J. L. Fisher. Agents of capitalists are in Walker district, examining properties belonging to C. V. Shelton. They think well of them, and may purchase. Mr. Graves has taken a fresh start in his deep placer claim on Hassayampa creek. He proposes to see the bedrock if it takes him all summer. The bottom of his claim is supposed to be chock full of gold nuggets.

#### COLORADO.

AT LEADVILLE.—Tribune-Republican, July 15: Leadville continues to maintain its unrivaled supremacy as the great ore-producing and ore-reducing camp of the Rocky Mountain region. The re-

serves of ore were never so great as at the present time, nor the indications for striking other bonanzas so certain as now. The faith in Leadville's ore treasures has increased year by year until not only observant men, but also all classes of citizens, are imbued with confidence in the permanency of her mineral resources. All kinds and conditions of people are interested in mining as a means of livelihood in Leadville, either as owners of claims or holders of leases. Everybody is mining for the money there is in the business. The scheme-worker has long since abandoned Leadville, and honest mining for mill settlements is now the rule, to which there seems no exception. Scores of camps in this State, which made a big blow about surpassing Leadville (when they had had time for development), can now humbly and profitably learn the lesson Leadville is so plainly teaching them, that steady work night and day with heavy shifts is the potent factor which delivers ore in bulk to the smelters. Leadville produces the most ore, but she also works more men, pays bigger bills, expends greater energy, takes heavier chances, and boasts infinitely less while so doing than any other mining camp in the State. The town of Leadville is so quiet and sedate nowadays that one can hardly imagine it as we knew it from 1877 to 1880. Earnest work for the extraction of ore or persistent work intelligently directed for the discovery of new ore chutes are the distinguishing features that impress one at Leadville, and are the reasons for her continued supremacy.

#### IDAHO.

THE STAR OF HOPE.—Ketchum Keystone, July 16: The Star of Hope mine is located on the headwaters of Lost river, opposite Muldoon, and the head of Little Wood river, in Custer county. It is now owned by Jos. Pinkham, Charles Ross and others, and is under the management of James Hickey, a well-known mining man of this region. Mr. Hickey left Ketchum last Thursday with new supplies, tools, etc., for the mine, and will immediately begin the construction of a flume and jigs for the concentration of large quantities of ore now on the dump. The water supply will come from a neighboring lake and the jigs will be built at the mouth of the main working tunnel. They will be ready for operation next week. A crew of 10 men will be employed during the summer. The ore vein of the Star of Hope is a remarkable one. It lies between lime and shale and porphyry—a contact vein—and it ranges from one to four feet in width. The ore is chiefly a heavy, high-grade galena, and has been practically tested by a recent shipment of 23 tons to the Philadelphia smelters, which netted \$3000.

THE IRVING MINE.—Mr. M. Cary, who has employed from 15 to 20 men on Boyle Mountain during the past winter and spring, has taken a new lease on the Irving mine, owned by the Philadelphia Mining and Smelting Co., which will not expire until June 1, 1887. He has already found new ore and is encouraged to believe that his new lease will prove fully as profitable, if not more so, than his former one. Forty tons of ore were recently worked at the smelters with satisfactory results.

ATLANTA.—Idaho World, July 15: Julian Hill arrived here last Friday from Atlanta. He says Atlanta is almost deserted. The mines there have not been worked out, as has been reported, but were shut down pending negotiations for sale. The Taboma has been sold, but the Buffalo and Atlanta companies have not yet effected a sale. The Buffalo mill will soon be running again. A man named Williams is putting a road through from Atlanta to Ross valley, a distance of six miles. A mill will soon be put up at the latter place to work ore from a gold-bearing ledge discovered years ago and abandoned. It was recently relocated. A pack-train has gone to Silver district to pack ore to Atlanta for reduction. The Ida Elmore Company, at Rocky Bar, will have a 50-stamp mill up and running at their mine the coming fall. The Idaho Elmore is 16 or 18 feet through—all pay ore—mostly low grade. With a small mill the entire ledge could not be worked at a profit. When the big mill goes up, all the ore from wall to wall will be crushed.

THE ASSAY OFFICE at Boise City now pays the same rates for gold dust and gold bullion that Eastern points and San Francisco do. So by disposing of dust and bullion at the Boise City office express charges to San Francisco or the East, amounting to about \$10 per \$1000, are saved.

PINE CREEK.—Coeur d'Alene Record, July 15: Friday afternoon Peter Lynam, from Pine creek, dropped in. From him we were pleased to hear from George Lemon, well and favorably known to many Murray people as a former employee of the Record. Messrs. Lynam, Lemon and Glick are the owners of the Burning King lode on Pine creek, about three miles from its mouth and about 10 miles from Wardner. It is said to show a well-defined three-foot ledge between slate walls. They have run in a tunnel 20 feet. Mr. Lynam tells us that there are probably 80 or 90 claims located on Pine creek, and about 50 men now prospecting there. We understand also that work will be commenced today on the building for the smelter to be erected at Pine Prairie. Several men are already engaged in getting out shakes for it. On the whole, the prospects of Pine creek appear to be very promising.

#### MONTANA.

THE DRUM LUMMON.—Helena Independent, July 15: During the month of June the 60 stamps of the Drum Lummon mills crushed 3065 tons of ore and cleaned up \$159,800 in gold and silver retort. The stamps were in operation, deducting all stoppages, 27 days in the month. This is the largest month's output the mine has ever made, and is, the Independent believes, the largest single month's return ever made to a quartz-mining company in Montana. The west side must now yield the palm to the east side for big outputs. The output of the Drum Lummon for the first six months of 1886 almost equals the total product for 1885. The figures are as follows: 1886—January, \$100,800; February, \$110,700; March, \$145,000; April, \$146,000; May, \$146,500; June, \$159,800; total, \$808,300. Total for 1885, \$850,000. It will be noticed that the figures for the six months of 1886 represent a constant progression, June crowning the list with \$59,000 more than January and over \$13,000 more than in the month preceding. It is safe to predict that the present month will exceed June, and when the company's

new mill is completed and in operation, which will be in September, it is beyond estimate to what fabulous figure the product of this immense mine may reach. The saving per ton of ore in last month's work was about \$52.15. This, it is needless to point out, means very rich ore.

THE GLOSTER.—The output of the Boston and Montana Mining Company for June is approximated by Manager Child at \$50,000.

BULLION AT THE ASSAY OFFICE.—By the courtesy of Mr. Spruille Braden, assayer in charge, the Independent is able to state that the total value of gold and silver bullion deposited at the United States Assay Office, at Helena, for the fiscal year ending June 30, 1886, was \$1,160,820.21.

AFFAIRS OF THE ELKHORN.—The Elkhorn mine is still flooded on the lower levels, simply because the pumps got swamped. When the new pumps ordered from Butte are set up, the water blockade will be raised. In the meantime, there will be no shortage in the milling results, as there is enough ore available for a year's work, even after the five new stamps are set up and in operation. It is a great property, and helps to swell the volume of territorial production of the precious metals. The Granite Mountain Mining Company paid its 20th regular monthly dividend of 25 cents per share yesterday, aggregating \$100,000; amount paid this year to date, \$620,600.

#### NEW MEXICO.

SOCORRO.—Bullion, July 15: One day this week 60 carloads of ore and material arrived for the Billing Works and Graphic smelter of this city. Eighteen carloads of ore passed Socorro on last Saturday consigned to Pueblo and Denver. This will satisfy the owners' ambition, and the balance will come to our Socorro plants. The output of gold from the mines at Golden is encouraging. Last Saturday Col. Webb, of Santa Fe, received the result of a three days' run of the Webb & Fish mill, which netted \$1550. Last week D. Langsdorf and J. Kelly made an important strike of high-grade argentiferous copper carrying gold, in their Quartzite mine of Water Canyon district. They will commence to ship ore on the 20th inst., and intend to follow this consignment at regular intervals. M. W. Bremen is pounding away at his amalgamating mill at Silver City, each stamp disposing of about five tons of ore per day. His improved machinery is working elegantly, and instead of having tailings containing, as heretofore, from eight to nine ounces, they do not exceed two ounces. There are at present 50,000 tons of ore in sight in the Graphic mine. The Graphic blew in the 80-ton stack on the 8th inst., and on Friday the 25-ton stack. The gold discovery creates intense excitement in Socorro, and mining men are arriving at Ruby camp from all directions. Nos. 2 and 3 stacks of the Billing smelter, with a capacity of 160 tons, are working under full blast. No. 1 will blow in shortly. Judge Keeney got over 30 colors of gold by washing one ounce of the Ruby gangue rock, in which no mineral was visible by the aid of a powerful mineral glass. The managers of the Flagler Reduction Works at Silver City are feeling very much encouraged. They have large quantities of ore on hand and in sight. Their matting furnace is nearly ready to blow in, and in a short time both it and the chloridizing furnace will be worked to their full capacity.

NOTES.—Socorro Bullion, July 15: Posey and Joyce are preparing to improve their Granger claim in Water canyon. The Homestake mine at Kingston, on the North Percha, is bonded for \$11,000. The Maggie Merchant and the General Canby are being worked in Water canyon. A rich company are about to commence extensive operations at Gold Hill, Grant county, N. M. T. H. Zeigler is delving systematically in his Index claim in Water canyon, with fine prospects ahead. When the price of bar silver, 1000 fine, in New York, is 97½, it is about 32 cents per ounce less than the assay value of that metal. The Magdalena Queen, an extension north of the Ruby, makes a fine showing of rich argentiferous lead ore. The property is owned by Gochenauer, Woodyard and C. T. Brown. It is not at all impossible that the Ruby lead traverses it. Millette is working in his incline on the lead lode. This claim is situated about 800 feet below the Ruby strike. He thinks he will have pay ore in a short time; he is sinking on precisely the same character of formation as found on the Ruby mine. Not over \$100,000 has been spent on the east slope of the Magdalena range in mining development. This is less than was expended in the Kelly alone, in exploring and opening up that property. Of this amount \$72,700 was expended in Water canyon.

#### UTAH.

REVIEW.—Salt Lake Tribune, July 19: The receipts of ore and bullion in this city for the week ending July 14th inclusive were \$190,745.90, of which \$73,572.98 was ore and \$117,172.92 was bullion. The previous week the receipts of ore were \$110,349.63; of bullion, \$152,663.48; a total of \$263,013.11. The product of the Ontario for the week was 20,782.14 ounces of fine bullion; ore sales, \$16,331.90. The daily output for the week was seven bars of bullion, \$9358.71; no ore sales. Base bullion receipts of the week, \$22,200; fine bars, \$30,200. The Hanauer smelter product for the week was \$27,215 in bullion; the Germania's, \$25,110.10. Ore receipts of the week were as follows: By Wells, Fargo & Co., \$26,513; by McCormick & Co., (including \$2485 Queen of the Hills and \$13,411 Crescent), \$36,171; by T. R. Jones & Co., \$10,888.98.

#### WASHINGTON.

COLVILLE.—Stephens Reporter, July 17: We learn that Mr. T. D. Fuller, one of the first prospectors of this camp, has struck a rich lead of ore on the headwaters of Deep creek, right east of the Old Dominion mountain, at the fountainhead of the Little Pend d'Oreille. The ore is what is called silver glance, and there is uncovered about five feet of actual mineral, and it will assay about \$300 per ton. On the north fork of Mill creek, Mr. Joseph Adams has discovered another rich lead of mineral, in which Mr. Fuller is interested. It is called by the classic name of Jump-off-Joe, and is in a district called Hog Em. This strike is galena and carbonates, and is about 12 miles from Colville,

# DAMAGED BY FIRE!

## Engines, Boilers, Wood and Iron Working Machinery, Belting, Etc.

### FOR SALE CHEAP!

The fire which destroyed our building, Nos. 25 to 31 Main Street, on the 20th of June, will have no effect on our business.

We have already secured one of the stores in the magnificent Donahue Block, Nos. 34 and 36 Fremont Street, near Market, the finest in the city.

We have removed our Machine Shop to Nos. 225 and 227 Beale Street, and are now in full blast.

Our Oil Warehouse is located at 519 Front Street.

Our Oregon Branch is still at 91 and 93 Front Street, Portland.

Constant arrivals of new stock will enable us to supply our customers with everything of the latest and best description.

In addition, we shall have all of our old stock of Machinery, much of which had just come in, removed from the burnt building to our new store, where we shall be able to offer it at **EXTREMELY LOW PRICES.**

When the fire occurred, we had, fortunately, finished shipping the mammoth mills for La Trinidad and Silver Queen Mines, of Mexico, and the 20-Stamp Mill for the Buchanan Mine, of Tuolumne.

Notwithstanding our fire, the Pacific Lumber Company, of Humboldt, awarded us the contract for their new mill over all competitors, preferring to wait till our New Shop was ready rather than get their Machinery elsewhere, though they are in a great hurry. We consider their action conclusive evidence of the superiority of our Machinery, as they are determined to have the finest mill on the Coast.

Our New Concentric Set Works and Headblocks, and the Sinker, Davis & Co. Band Log Mill, which we recently furnished the Humboldt Lumber Company, of Humboldt, are pronounced by them superior to any ever seen in Humboldt.

We are now at work on nine Headblocks for Pope & Talbot Mills on the Sound.

From the above facts, it would appear that we stand fire pretty well, and if our patrons will kindly continue to favor us with their valuable business, we will do our best to excel our former efforts.

## IMPORTANT TO GOLD MINERS!

### SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.

**BEST SOFT LAKE SUPERIOR COPPER USED.**

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

**SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.**  
**E. G. DENNISTON, Proprietor.**

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

## CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

### Sporting, Cannon, Mining, Blasting and

## HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

**No. 1 (XX) is the Strongest Explosive Known.**  
**No. 2 is superior to any powder of that grade.**

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

THE CONSUMERS' COMPANY.

## VULCAN B B AND AJAX.

The Best LOW GRADE EXPLOSIVES in the Market.

## Metallurgy and Ores.

**SELBY  
SMELTING and LEAD CO.,**

416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY  
And Assay Office.

Highest Prices Paid for Gold, Silver and  
Lead Ores and Sulphurets.

...MANUFACTURERS OF...

BLUESTONE,  
LEAD PIPE,  
SHEET LEAD,  
SHOT, Etc., Etc.

ALSO MANUFACTURERS OF

Standard Shot-Gun Cartridges,  
Under Chamberlin Patent.

**JOHN TAYLOR & CO.,**

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE  
AND MILL SUPPLIES,

CHEMICAL APPARATUS AND CHEMICALS, DRUG  
GISTS' GLASSWARE AND SUNDRIES, ETC.

114-118 Pine Street, - San Francisco.

We would call the attention of Assayers, Chemists,  
Mining Companies, Milling Companies, Prospectors, etc.,  
to our full stock of Balances, Furnaces, Muffles, Crucibles,  
Scorifiers, etc., including, also, a full stock of  
Chemicals.

Having been engaged in furnishing these supplies since  
the first discovery of mines on the Pacific Coast, we feel  
confident from our experience we can well suit the de-  
mand for these goods, both as to quality and price. Our  
New Illustrated Catalogue, with prices, will be sent on  
application.

Our Gold and Silver Tables, showing the value per  
ounce Troy at different degrees of fineness, and valuable  
tables for computation of assays in grains and grammes,  
will be sent free upon application. Agents for the Patent  
Plumbago Crucible Co., London, England. Also for E.  
G. DENNISTON'S Silver Plated Amalgam Plates. The  
plates of this well-known manufacturer are thoroughly  
reliable, and full weight of Silver guaranteed. Orders  
taken at his lowest prices.

JOHN TAYLOR & CO.

**Nevada Metallurgical Works.**

NO. 23 STEVENSON STREET,

Near First and Market Streets, S. F.

C. A. LUCKHARDT, Manager. ESTABLISHED 1869.

Ores worked by any Process.

Ores Sampled.

Assaying in all its Branches.

Analyses of Ores, Minerals, Waters, etc.

Working Tests (practical) Made.

Plans and Specifications furnished for the  
most suitable Process for Working Ores.

Special attention paid to Examinations of  
Mines; Plans and Reports furnished.

C. A. LUCKHARDT & CO.,

(Formerly Huhn & Luckhardt),

Mining Engineers and Metallurgists.

The Most Durable!

ADAPTED TO ALL KINDS OF WORK,  
Send for Catalogue! AND MADE IN STYLES AND SIZES TO SUIT.

THE FOOS MANUFACTURING CO., - - Springfield, Ohio

## ADAMANTINE Shoes, Dies and Crusher Plates

We manufacture the above Adamantine  
Shoes, Dies and Crusher Plates. They are in  
use on the hardest quartz in the United States  
and South and Central America, and have been  
for the last ten years; we warrant them to out-  
wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times  
longer than any other make. They never break AT THE SHANK, and the wear is so light  
that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.  
For further particulars, address

**CHROME STEEL WORKS,**

H. D. MORRIS, Agent, 22 Fremont St., San Francisco.

When ordering, a rough sketch, with full dimensions, is all that is necessary.

## CHILLED CAR WHEELS.

Medal Awarded Mechanics' Fair, 1882.

No. 137 FIRST STREET, SAN FRANCISCO, CAL.

IRON CASTINGS OF ALL DESCRIPTIONS.

## List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey &amp; Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in DEWEY &amp; Co.'s Patent Office Library, 252 Market St., S. F.

FOR WEEK ENDING JULY 13, 1886.

- 345,404.—CHECK REIN ATTACHMENT—C. L. Bard, San Buenaventura, Cal.  
 345,567.—PIPE WRENCH—S. J. Benson, Boulder Creek, Cal.  
 345,280.—HEAT REGULATOR FOR INCUBATORS—L. H. Cutting, Stockton, Cal.  
 345,371.—TWO-WHEELED VEHICLE—S. P. Davis, Napa, Cal.  
 345,373.—ANIMAL EXTERMINATOR—H. Esborn, Petaluma, Cal.  
 345,385.—EXPANDING DRILL-BIT—C. C. Lane, S. F.  
 345,388.—SAW GUMMER—S. R. Mathewson, Porterville, Cal.  
 345,391.—STEAM COOKER—D. D. Mounts, S. F.  
 345,395.—BARREL-TILTING DEVICE—Potter & Gomez, S. F.  
 345,396.—KEY-HOLE GUARD—Katy Rumetsch, S. F.  
 345,333.—STEAM GENERATOR—J. E. Taylor, Walla Walla, W. T.  
 345,461.—CANDLESTICK—Samuel Tyrell, Grass Valley, Cal.  
 345,345.—GOPHER TRAP—John Weichhart, S. F.
- NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

## Mining Share Market.

Mining stocks have been more or less active this week, though there has been no actual advance in prices. The election of the Savage Mining Company insures an active management for the year, and important explorations have been projected. The west face of the station for the 3200 level from the Combination shaft, which was promptly stopped when the good ore vein was struck, will now be as promptly developed by straightforward advancement. A new drill hole in Potosi to exploringly crosscut the heavy ore vein found to exist to the east on the 3100 level, has been started, and more will be known regarding this good ore vein very shortly.

The north lateral drift from the Combination shaft 3200 station, to connect with the deep winze of the Hale and Norcross, on that level, is being energetically pushed ahead, and is now into Hale and Norcross ground. About 100 feet remains to be excavated to make connections with the drift south from the deep winze.

The work at the Osbiston shaft is confined to the preparations for deeper sinking. The rumored ore strike in Ophir, unfortunately, is officially pronounced to be a false alarm. The low-grade ore bonanzas of the Consolidated California and Virginia and in Yellow Jacket, Crown Point and Belcher, continue their regular yield.

It is stated that John W. Mackay will take position as superintendent of the north end mines, in place of W. H. Patton, who will go off on a vacation for two or three months.

## Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Argus, July 17, \$7000; Martin White, 17, \$5900; Odessa mill, 18, \$6800; Oro Grande mill, 18, \$6359; Barbers mill, 18, \$6000; Hanauer, 13, \$904; Crescent, 14, \$3881; Germania, 14, \$8125; Hanauer, 15, \$5625; Germania, 16, \$1861; Hanauer, 16, \$2970; Queen of the Hills, 16, \$1335; Hanauer, 18, \$6200; Pascoe, 18, \$1365; Queen of the Hills, 18, \$1490; Alice, 20, \$14,530; Germania, 20, \$3805; Hanauer, 20, \$8950; Stormont, 18, \$3350; Queen of the Hills, 20, \$1350. Through Wells, Fargo & Co., Salt Lake, last week, \$78,913; McCormick & Co., \$53,386; T. R. Jones & Co., \$35,999; and Union bank, \$12,447.

## Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

## Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

JARED C. HOAG—California.  
 G. W. INGALLS—Arizona.  
 E. L. RICHARDS—San Diego Co.  
 E. G. HUSTON—Idaho and Montana.  
 GEO. McDOWELL—San Luis Obispo and Santa Clara Co's  
 FRANK W. SMITH—Idaho and Montana.

THE more misfit institutions, the better for Muller, the Optician, 135 Montgomery St., x

## Haywards Hotel.

We take pleasure in calling attention to this well and favorably known resort. It has been long established and popular. The locality is elevated and healthy, the surroundings pleasant in the midst of the fruit region of Alameda county. The table will be found supplied with the best in the market, and the proprietor intends to spare no pains in making his house a pleasant and popular home for tourists and pleasure-seekers. Further particulars will be seen in the advertisement in this paper. San Franciscans and Oaklanders find it a very convenient and delightful place to tarry.

## Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

**HEALD'S BUSINESS COLLEGE,**  
 24 Post St. S. F.  
 Send for Circular.

## Inducements to Subscribers.

To favor subscribers to this paper, and to induce new patrons to try our publication, we will furnish, to those who pay fully one year in advance of date, if requested, the following articles (while this notice continues) at the very greatly reduced figures named at the right:

- 2.—World's Cyclopedia, 794 pages, 1200 illustrations (exceedingly valuable). \$0.50
- 3.—Dewey's Patent Elastic Binder (cloth cover), name of this paper stamped in gilt. .50
- 6.—To New Subscribers, 12 select back Nos. of this paper. Free
- 7.—Any of Harper's, Frank Leslie's and most other first-class U. S. periodicals, 15 per ct. off regular rates.
- 9.—Pacific Coast and Eastern Dailies, Books and Periodicals, except special publications, we can usually give 10 to 15 per cent off advertised retail rates.
- 10.—Picturesque Arizona, 380 pages, in cloth and gilt. .25
- 11.—Californian, 100 pages, Magazine, 1880 to 1882 (3 Vols.) single Nos. .03
- Per volume, unbound, 5 Vols. .20
- Per volume, bound, cloth back and stiff paper sides, about 600 pages. (Send two-cent stamp for sample). .40
- 14.—Dewey's Pat. Newspaper Fileholder (18 to 36 in.). .25
- 15.—Life among the Apaches, 322 pages, stiff cloth. .15
- 17.—Architecture Simplified, 60 pages. .25
- Webster's Dictionary, 634 pages, with 1500 illustrations; very handy and reliable. .50
- De Groot's History of Mining in California, 16 pages. .05
- Beautiful Poetic Review, entertaining and instructive, 35 pages (a handsome and pleasing present). .25

**CALIFORNIA**  
**ARTIFICIAL STONE PAVING CO.**  
 (SCHILLINGER'S PATENT.)

FOR—  
 SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE  
 DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

## HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

## JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over all  
other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impos-  
sible to make them tight except by regrinding, which is expensive if done by hand, and if done  
by machine soon wears out the valve, and in most cases they have to be disconnected from  
the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is  
manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited.  
To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by  
DUNHAM, CARRIGAN & CO., San Francisco, Cal.

## SQUARE FLAX PACKING.

Finest Packing in the world. Trial Samples sent free. Send for circular. Best of ref-  
erences. Manufactured by W. T. Y. SCHENCK, 256 Market St., San Francisco.

# \$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,  
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.**  
(\$575 00), F. O. B.

**OVER 1,000 ARE NOW IN USE.** Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco. As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement. The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them. Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1885. Patents applied for. N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

**GET THE BEST.**

## The BARAGWANATH STEAM JACKET FEED WATER HEATER AND PURIFIER.

Adapted to High & Low Pressure Engines.  
**OVER 5000 IN USE.**

The advantages of this Heater, briefly stated, are as follows: It loses no heat by radiation. That portion of the water chamber which in all other heaters is subject to the cooling action of the atmosphere is converted into a heating surface by the Steam Jacket. It has twice the heating surface of any other of equal size.

It delivers its water always above the boiling point, averaging from 215 degrees to 220 degrees. By boiling the water under pressure all impurities are thrown off.

It keeps the Boiler clean and free from scale, by which means a large saving in fuel is effected, as also a great saving in repairs, as well as the capacity of the Boiler largely increased.

It never causes any back pressure on the Engine, but acting as a surface condenser relieves any back pressure that may exist. Send for Circular.

A. P. BRAYTON, Jr.,  
Agent for the Pacific Coast.

PACIFIC IRON WORKS,  
127 First St., San Francisco, Cal.

**GET THE BEST.**

## THE BARAGWANATH HEATER.

WHAT IS SAID OF THEM BY  
PARTIES USING THEM.

"Heats water to 220 degs."

St. Louis, Mo., August 24, 1885.

Messrs. Wm. Baragwanath & Son, Chicago, Ill.—GENTLEMEN: We take pleasure to inform you that your Steam Jacket Feed-Water Heaters have given perfect satisfaction. We work the same in connection with three batteries of boilers, representing 650-horse power. They heat the water to 220° Fahr., and we warmly recommend them to all establishments using steam machinery. Yours truly,

ANHEUSER, BUSCH BREWING ASS'N.  
GEO. KRUMSICK.

WOODMAN LINSEED OIL WORKS,  
OMAHA, NEB., Dec. 21, 1885.

Messrs. Wm. Baragwanath & Son, Chicago, Ill.—GENTLEMEN: Your heater is working to our perfect satisfaction. Temperature of feed-water is 218° and purification is perfect. From all appearances the heater is in perfect condition. It has been in constant use for three years. Yours truly,

CLARK WOODMAN, Pres.

Wm. Baragwanath & Son—DEAR SIR: In answer to your favor of the 11th inst., we beg to state that we have purchased a large number of your Heaters for use of mining companies in the West and foreign parts. We have always received the highest possible testimonials regarding the operation of the Heater, and personally, we consider it equal to any Heater in the market, and give its use preference at all times. Yours truly,

FRASER & CHALMERS.

**GET THE BEST.**

## THE BARAGWANATH HEATER.

WHAT IS SAID OF THEM BY  
PARTIES USING THEM.

Saves a ton and a half of Coal per day.

F. MAYER & Co.,  
Manuf'rs Furniture, 300 to 341 S. Clinton St.,  
CHICAGO, August 23, 1880.

Mr. Baragwanath—DEAR SIR: We have been using your Steam Jacket Heater for several months, and find it fully up to your representations. It saves us about a ton and a half of coal per diem, and gives us a regular steam pressure. It works to our entire satisfaction in every respect. Yours respectfully,

F. MAYER & CO.

## PULLMAN PALACE CAR CO.

PULLMAN PALACE CAR WORKS,  
DETROIT, Mich., Feb. 25, 1882.

I beg to report the Steam Jacket Feed-Water Heater and Purifier, made by Baragwanath, of Chicago, has been in operation in our works for some time, and from careful test I find the heat of feed-water delivered from Heater 215 degs. Fahr. I do not find any visible back pressure on the engine. The engine had eight pounds of back pressure when working in connection with our old Heater. We save 30 per cent in fuel, and ONE FIREMAN. We have dryer and hotter exhaust for warming shops than before. I also find the Heater the best apparatus for removing scales I have ever seen.

CHARLES MERRY, Chief Engineer.

**GET THE BEST.**

## THE BARAGWANATH HEATER.

WHAT IS SAID OF THEM BY  
PARTIES USING THEM.

"Boiler Clean as Possible."

OFFICE OF CHAS. FIGLER,  
Manuf' of Flour, Feed and Meal,  
NEW AUBURN, MINN., March 11, 1882.

DEAR SIR: In response to your inquiry about the working of the Baragwanath Heater I bought of you last summer, would say it is the best Heater and Water Purifier to my knowledge. I would not be without it for twice its cost. My boiler is as clean and free from scales as it is possible to be, and I invite steam users contemplating to buy a Heater to come to my mills and examine mine before they buy elsewhere.

Respectfully yours, CHAS. FIGLER.

STANTON, MICH., March 17, 1881.

Wm. Baragwanath—DEAR SIR: After two years' use of the Heater, we can say your guarantee has been fully met. It delivers its water into the boiler at 217 Fahr., purifying it to a very great degree, and saving fully 20 per cent of fuel. No new scale has formed on the boiler since its use. It is a success, and the best Heater we have any knowledge of. Yours truly,

TURNER & REYNOLDS.  
October 30, 1885. Does all it ever did; never had a cent's repairs; know of nothing which equals it.—T. & R.

DETROIT LINSEED OIL COMPANY,  
DETROIT, Nov. 24, 1885.

Wm. Baragwanath & Son, Chicago—GENTLEMEN: We are using your Steam Jacket Heater and Purifier with great satisfaction, obtaining at all times the best results. Yours truly,  
SAML E. PITTMAN, Manager.

## Temporary Steering Gear.

Capt. C. F. Swan, of this city, has devised a very simple and ingenious plan for steering a ship or steamer having a disabled rudder, and one which is so easily constructed that we have had engravings made to show the plan. It is not patented. The main feature is the method of securing the plank or drag to the steering lines or guys. A 16-inch plank, 16 feet long and 2½ inches thick, has iron bridle secured to it, one arm of the bridle being longer than the other. Then, when the strain comes by the motion of the vessel the plank is dragged at such an angle (the long arm being uppermost) that it submerges itself, no weight being necessary. The base inclines toward the ship, so the plank is kept down. The plank is veered astern by the guys. The inner ends of the guys are secured to the ends of a pivoted brace, and tackles led from these ends to the barrel of the wheel of the ship, so that it can be steered from the wheel.

The upper figure of the cuts shows the drag or temporary rudder towing directly astern, in line with the keel. The next figure shows it turned to one side, so as to swing the ship's head in the same direction. When the temporary rudder is swung to "port," it swings the ship's head to "port" and vice versa.

The bumpkin or spar projecting over the stern of the vessel is simply a matter of commerce, as the pivot could be put on the taffrail itself if necessary. In fact even the pivoted bar can be dispensed with, but it is more labor to use the device. The third, or lower engraving, shows, for instance, how the great steamer *Alaska* could have been steered when she lost her rudder, and they had so much difficulty managing the huge vessel. If they had rigged the bridled plank, the guys or steering lines could have been led to the quarters, and by slacking on one line and hauling on the other, the vessel could have been steered.

The faster the vessel goes the easier she will steer, as the drag is hauled down at an angle deep under water and gives resistance. It will not "tack" a ship because, as she comes in stays she slows up, and the drag rises to the surface. But it will "wear" a ship; that is, turn her from one tack to the other by running her off before the wind. Brace lines (shown in the upper figures) help strengthen the center of the plank.

If the ship is low in the water the guys or steering lines need not be very long, but if high out of water—say 25 or 30 feet—they should be 25 or 30 fathoms long. Capt. Swan used this steering gear on the *City of Brooklyn*, a 1700-ton ship, for two days without the slightest trouble. If the vessel goes slower than four knots an hour, the drag does not do as well, as it is apt to rise to the surface, where it is not so efficient. The gear used on the *City of Brooklyn* did not cost over \$100. The size of the drag should be in proportion to the vessel, but it should present a flat surface, as shown, and the bridle must be made as shown, to be effective. A large ocean steamer could have this gear ready at hand for use in case of accident to the rudder. It is the simplest device of a practical nature which has come to our notice.

ACCORDING to the *Merced Star* a talc mine has been discovered on J. W. Minges' farm on the Merced river. The material abounds in large quantities at the place of discovery.

A PACIFIC COAST CRUISER.—A Washington paper, devoted largely to army and navy matters, prints the following in regard to the new cruisers: "It has been suggested that one of the new vessels should be delivered to the Government at San Francisco by the contracting parties. This would give the builders in Cali-

THE IRON WORKERS.—A Conference Committee of the Iron Trades Council has met the representatives of the Union Iron Works. The committee asked for the discharge of the non-union men, promising to make some arrangements by which they should not suffer for the loss of work, and further, that all the men

## Meadow Lake Again.

Meadow Lake district, Nevada county, five miles off the south boundary of Sierra county, is often referred to as one of the most striking examples of an abandoned mining camp. Years ago there was a wonderful excitement there and a town sprang up suddenly with brick buildings, hotels, warehouses, dwellings, quartz mills, etc. It did not take very long, however, to find that the ore was very rebellious. All sorts of plans were tried to work it, but they failed. Then the town was deserted; mills, hotels, buildings, etc., were abandoned, with all their contents, until only one or two men were left in the camp. Periodically since then a small excitement has been started, and some new processes inaugurated for working the ores. Some few persons have had continued hopes of improvement and have "hung on," but thus far all the trials to work the ore profitably have failed. Once more, however, a trial is to be made, and a prediction is made that there is to be an immediate revival in Meadow Lake. The *Truckee Republican*, in speaking of it, says: "There is to be an immediate revival in Meadow Lake mines. Several capitalists from below are interested in a new process of treating rebellious ores, and propose to try results on ore in that district, with every prospect of success. The machinery which attracted the attention of the reporter is the 'plant' to be used in the operation. It consists of the following items: First, a rock-breaker or crusher; second, a large cast-iron machine which looks as though it was to be used to grind the ore; third, two iron cylinders about six feet long, probably rotary ore roasters; fourth, a concentrator of new device; fifth, a small dynamo and electrical apparatus; also numerous shafts, pulleys, pipes, etc. It is consigned to A. P. Whittel, in care of S. C. & Co. The gentleman mentioned will be here in a few days, and more complete details of contemplated operations will be ascertained. There are a dozen or more men at the mines, and there will be a large amount of development done there this season. It will be a day of great rejoicing when a successful process of treating Meadow Lake ore can be discovered."

THAT "SULPHUR" SHOWER.—It was announced in the dispatches and newspapers of last week that a shower of sulphur had fallen at Carson, Nevada, covering the ground to the depth of from one-sixteenth of an inch to an inch deep. Quite a number of persons were satisfied it was sulphur, and the explanation was that a waterspout took up the sulphur from some lake and deposited it where found. The material, however, instead of being sulphur is found to be nothing except the pollen of pine trees. This fine, fertilizing substance is present in the atmosphere at this time of the year, and is frequently borne by the winds for a long distance. Of course, a heavy shower will precipitate it, sometimes in large quantities. Donner lake, the *Truckee Republican* says, was recently covered with it.

AN ECONOMICAL ARRANGEMENT.—At the Kentuck mine, on the Comstock, a Pelton water wheel on the 700 level, placed at the head of the winze, does the hoisting from the 800 and 900 levels. Its motive power is the seepage from the upper levels of the mine, with a pressure of 540 feet. This is a very economical and advantageous arrangement in the cost of working the mine.

SWAN'S DEVICE FOR TEMPORARILY STEERING VESSELS.

ornia a chance to compete with Eastern men, and would not cost the Government a dollar more if the vessels should be needed for the Pacific Coast. That one of these vessels should be sent out to the Pacific, there can be no question. Our interest on the west coast is increasing every day, and the only vessels now there are old, antiquated wooden vessels, built before and during the war, and they are decaying as rapidly as possible. These ships were good enough in their day, but that has passed. The Secretary should do all in his power to encourage the mechanical industries of the Pacific."

should be discharged and the works shut down for a week. The union would then select men who were not objectionable and the works could be started up. Mr. Dickie would not hear of the proposition, and refused to yield an inch from the original situation before the men struck. After an hour and a quarter's useless discussion the committee withdrew.

THE Arrow gold camp, near Calico, is shut down for the present. The last carload of ore shipped went three to five ounces in gold and five ounces in silver.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

## Gold Produced and Saved by Electricity.

EDITORS PRESS:—Some two years ago I endeavored to bring before the notice of the mining world, in your valuable paper, the urgent necessity of adopting some better method of saving gold than the stamp, mortar and copper-plate amalgamation; still, we are running along in the same old rut, really saving only by this old system not over 60 per cent, where the gold is fine. What a sad truth for our political economists to contemplate! How is it that this needful change cannot be brought about? Cannot our Legislature appoint a commission of practical men to devise some scheme by which this waste may be arrested? One reads endless discussions on the merits and demerits of stamp mills versus various and manifold forms of crushers, be they rollers—centrifugal or otherwise. A great deal of wasteful energy is thus thrown off by such controversies, whereas the main point is passed by. Any of these various mills are good enough in their way, so far as crushing ore is concerned. In where is the gain to crush so many more tons per day, if we cannot save the gold? Why, it is only creating more waste, exhausting the mines sooner and making a still greater loss; better to crush less and save more of the gold. This is simple economy. Then, let us discuss the best system of gold-saving.

Shall it be the "dry process"? In my mind it is far better than the wet; for is it possible to save "fine" gold by running it over copper-plates, with water flowing down-stream? But is not this the usual method of to-day? Thereby the purest and finest gold is lost—a very natural conclusion, or rather result. Tons of that same material are yearly lost in the mills all over the world, for the simple want of a better method of treating the precious metal. We have not materially advanced in this particular for the past 25 years. Is there no one bold enough to come forward to advance a plan by which a change in our system may be effected? But this change must be radical; my humble belief is that electricity is the power and the agent only that will create a new state of things in this particular, whereby fine gold now lost may be saved. I believe the present age will see auriferous rock disintegrated atomically, and the gold, no matter how fine, will be saved by agglomeration into one mass, by electricity, without the aid of any stamp mill, crusher, pulverizer, etc.; and better still, dispensing entirely with that very costly and much-wasted article, quicksilver.

Our great "Professor Edison" must look to his laurels, for most certainly the process will come, from facts known to myself, sooner or later. The baby will be born which will revolutionize gold-saving and prevent the present fearful waste and loss. I am more than ever convinced that electricity is the potent agent that has given us this precious metal in nature, and on the principle of "*Similia similibus curantur*," will, if we seek its aid, save it for us in its treatment. We, as miners, are striving tooth and nail to find and unearth this metal; and yet to know that so much is lost after all the dangers and cost of its extraction, brought to the surface only to be swept down again to the bottomless ocean. What little satisfaction is there in this direful fact? Let us ponder awhile. There cannot be day without night; there cannot be darkness without light; neither can there be positive electricity without negative. Now, assuming we have both these natural forces as terrestrial electrical currents traversing on, as well as in, the body of the earth's crust, the positive running in a north and south direction, shall we not have a negative current of an east and west course, crossing the positive at right angles? The fissures of the earth in gold-bearing regions, being filled with quartz, are the conductors of the positive force in the northerly and southerly direction.

Then, we find the dikes, or east and west series, conducting the negative currents to the point of contact, to or within the vein. The primary constituents of gold, according to my theory, were originally in a vaporous or fluid state, suspended in the north and south series. It was then, in its passage, arrested, transformed by the negative and positive action. The vapor or fluid matter became solidified and metallized, so to speak, deposited in the matrix in the form and character we now find it. Gold, the same agent, then, that produced it in nature, may it not now be used as a collector? I infer electricity produces crystallization of baser metals, catching up the iron, lead, copper, etc., mechanically holding particles of gold in its base embrace, these base metals being held in vapor or fluid state in the same manner as gold, and acted upon by the same agent, electricity, likewise solidifying it. Let us reflect. Do we ever find gold in matrix without iron? Firstly, and most largely, iron being a ready conductor of electricity, its presence is needed, and is always found wherever gold is, in some form or other. Lead and copper may be more secondary, but not as a necessity, for we do find gold without them. The iron is not chemically combined, but found in the matrix, gangue or bases, always near unto gold at all times.

Has not any miner that observes, seen that

where a crossing, as they call it, or negative seam, striking at right angles into the main vein, at or about that point his best pay ore—in fact, a "pay shoot"—is found? The walls may not show it, but if he explores into the wall he will find the indication sure, for no "pay shoot" will ever be found without such an indication; be it crossing of dike or thread, ever so small, it will be there as a negative conductor, which has caused the deposit of gold so found. I have held these opinions for over 30 years, have carefully studied these signs, as mentioned, in various parts of the world—Africa, Australia, New Zealand and California—until I am led to believe its truth, having in each country found as I have described. I am adverse to the theory of the natural chlorination of gold, as a general and accepted fact. The protoxide of iron present or not, as a precipitant, I cannot conceive nature making such a tedious laboratory test, when, in my opinion, electricity would, and can, arrive at the same end, and more quickly, by a single *coup de main*. Having now assumed in my opinion that electricity is the agent that by its positive and negative action produced the gold, so electricity is, and will be, the coming agent to extract it from the matrix, and finally save it, being now by science, so bridled and held in such subjection, must be made the future concentrator and collector. I do not propose, for space will not permit me, to go deeper into the matter, but will leave the question, for the present, with wiser heads than mine.

I have spent almost a life time in mining, and have been a close observer of the mysteries under the earth, and a more interesting study nowhere can be found. Books will not teach us everything. Practice is required, which is the helpmate of theory, but the aid of the scientist is needed here to determine whether there is anything or not in the theory I have thus crudely promulgated. Facts are stubborn things. The negative electricity plays as an important factor as the positive in electro-plating. The two combined under certain circumstances produce the beautiful wonders of art in our great electro-plating establishments—look for the parallel in the earth. Electro-plating is a plagiarism already shown to us in nature in the wonders of her terrestrial laboratory. Volcanoes, what are they but masses of latent pent-up gases made destructive by electricity? Gold has been discovered in Queensland, Australia, in the new geyser deposits, which are volcanic in their nature—principal agent electricity. There is found the negative and positive structures that conducted the electrical fluid, to my mind. Sandstone is the matrix there, the dikes causing or helping to produce the electrical action, hence the gold. Again, more especially may be observed in pocket mines here, where there is a well-developed "ore shoot," the negative crossing is always to be found, and often covered over with "black carbonate of iron" at point of contact with vein—again the result of electricity which miners call a "fuse." In pocket mining no gold is found, nor never will be, where there is no crossing or negative action, and found nearly always at right angles to main gold-bearing vein. In pocket mines the electric action is more direct and concentrated, in milling veins more generally diffused, but the same factor is present in both cases.

The whole earth's surface is one vast electrical machine, in the earth, on the earth and above the earth. W. F. DRAKE.  
Sonora, Tuolumne Co., Cal.

## Optimism of Miners.

EDITORS PRESS:—In your number of the 3d inst., I notice you copy from the *Chronicle* an article which to me seems full of prejudice and untruth against miners. Is it meant to be stated that the veteran miner falls into the wholly inexcusable error of mistaking gangue for ore, pyrites for gold and copper-stains for chloride of silver as a generality? I believe not.

Now, sir, when a paper thus stigmatizes and abuses the pioneers of California, I cannot but resent it in the most indignant terms, as I consider such attacks on the noble and generous class of prospectors and miners generally to be a wanton insult to the whole community that now are reaping the reward from the enterprise, sagacity, skill and truthfulness of the California pioneer and miner.

The statistical information of the gold and silver produced by this much-abused class yearly since '49 best refutes the slander of "veteran miners and prospectors" mistaking gangue for ore, pyrites for gold, and copper-stains for silver. Aye, sirs. When such slanders appear against a should-be honored class, we are apt to say that the newspaper press has ceased to be considered a conservator of public rights or morals, and is almost lost in popular contempt.

"Ye pioneers who braved the storm,  
And hewed the State to beauty's form!  
These are thy handiworks to emulate,  
That gives the prestige to the Golden State,  
And spread abroad an envied name  
Upon the page of history's fame."

"Oh, lead me back to forty-nine!  
Oh, give me back to-day  
The good old times of Auld Lang Syne,  
As now I close my lay."

OPTIMIST.

## Common Sense Geology.

NUMBER 4.

[Written for the PRESS by JUSTIN CHENOWETH.]

If geologists were right, globules of molten lead falling from the top of a tower, and solidified by cooling before reaching the bottom, would show a wrinkled surface and vesicular body instead of a smooth surface and solid body, which they always do. There is nothing to warrant the assumption that the existing configuration of the earth's surface in its details has to any great extent been produced by a contraction of the interior. It is much more probable that any effect on the surface resulting from contraction was more nearly assimilated to the character of surface cracks, such as are produced in a lump of clay drying in the sun, rather than crumpling or folding. One single circumstance proves that mountain ranges could not have been formed in that way. Had it been so, strata on the sides of them must in all cases have been inclined away from the summit. I know, of my own observation, that it is not so in the Sierra and Cascade range, and Humboldt states that it is not generally so with mountain ranges in any part of the world which he had visited; furthermore, that in some parts of the Alps the inclination of the sides was inward. If, at the time the mountains were formed, the main body of the earth was in a molten condition, having only a thin, solid crust, produced by cooling, the crust would certainly be thinnest and least rigid within the tropics. The consequence of that condition, coupled with the natural effect of centrifugal force, would inevitably be that all the principal mountain chains, had they been produced by the crumpling process, would lie in tropical regions having a general parallelism with the equator, while the subordinate ranges would chiefly appear in the same region, but lying at right angles to the former. It is hardly necessary to state that the actual condition does not show the least tendency to such an arrangement.

## Phenomena Connected With Mountains.

All phenomena connected with mountains afford reasons for concluding that most probably they are, in the main, simply sedimentary accumulations resulting from peculiar currents while the surface of the earth was entirely covered with water. Geologists do not controvert the allegation of a universal deluge by any argument. They simply meet it with an asseveration of its utter impossibility; yet they are obliged to admit that every explored portion of the land surface, even the highest mountain ranges, have, at some period, been covered by the waters of the ocean. They get over this difficulty by assuming that detached portions of land have been by some means successively elevated and depressed in such manner, that in course of time every portion of the land surface has been placed beneath and again elevated from the waters of the ocean, the level of the ocean, in the meantime, remaining immobile. I will show, by incontrovertible argument, that such an assumption as that is contradictory to their own theories. Formerly the drift phenomenon was supposed by geologists to be confined to the higher latitudes of the northern hemisphere, but about 20 years ago Agassiz created a sensation by declaring that it certainly occurred in Brazil within the tropics. It must now be admitted that it is manifest everywhere, both in the northern and southern hemispheres; that toward the close, at least, of that epoch the land where it occurs must have been beneath the waters of the ocean; that it exhibits everywhere a remarkable identity of lithological character; that there appears a general similarity of fossils, both animal and vegetable, associated with it, seemingly, in a great measure, independent of the latitude of location, in so far as their habits might relate to their living congeners.

## Teachings of Geologists.

Geologists always teach that neither the depression nor the elevation of large bodies of the land surface ever occurred suddenly, but that any considerable movement either way occupied an immense interval of time. They teach also that from the time of the first introduction of organic forms there has been a continuous extinction and progressive change of species. Now, if these three propositions were true, namely, that the depressions and elevations occurred piecemeal; that for the culmination either way an immense period of time was requisite; that in the meantime a progressive change of species was transpiring, the fossils of the drift deposit could not possess the universal similarity which they exhibit in all parts of the world, for, during the interval of time that must elapse between the habitancy of the first and last portions, there would be a marked change of species. Geologists attempt to explain the occurrence of tropical fossils being associated with the drift in high latitudes, and also in like manner the existence of Arctic fossils in the temperate and torrid zones, by presuming a temporary reversal of climate during the habitancy of the animals, or the growth of plants which these fossils represent. I will prove the fallacy of this explanation. Lyell, in his "*Elements of Geology*," when describing a portion of the Norfolk coast, in England, specifies three species of elephants, one of the rhinoceros, hippopotamus, common pig, horse,

bear, wolf, bison, deer, reindeer, beaver, walrus, narwhal and others, including altogether about 20 species, all now lying together in the same bone bed.

## Remains of Animals.

Hugh Miller, the great geologist, in one of his lectures on the geology of Scotland, while describing the boulder clay or drift of that country, says: "When this Norwegian pine flourished in Britain the island was inhabited by a group of quadrupeds now never seen associated, save in a menagerie. Mixed with the remains of animals still native to our country, such as the otter, the badger and red deer, there have been found skeletons of the tailless hare, now an inhabitant of the cold heights of Siberia, and horns of the reindeer, a species now restricted in Europe to Northern Scandinavia and those inhospitable tracts of Western Russia that border on the Arctic sea. And with these local forms there were associated, as shown by their bones and tusks, the elephant, the rhinoceros and the hippopotamus." In a paper read before a British scientific association on the exploration of Kent's cavern in Devonshire, there occurs the following statement, viz.: "Two thousand and two hundred teeth exhumed since August, 1870, belonged to different animals in the following ratio: Hyena, 335 per thousand; horse, 295; rhinoceros, 161; Irish elk, 55; ox, 35; deer, 27; badger, 22; elephant, 20; bear, 18; fox, 12; lion, 6; reindeer, 5; wolf, 4; bat, 2; rabbit, 1." These are not singular examples. They are typical of this universal feature of the drift wherever it has been carefully explored. The same incongruous admixture of fossil plants nearly always occurs in the drift. There could not have been any large rivers in that region at that time, by means of which those animal remains should have been brought together from climates of great dissimilarity. By the popular theory, therefore, notwithstanding the extreme difference of their natural requirements in relation to food, temperature and constitutional habits in nearly everything, the living animals from which they were derived must have been congregated very nearly within the same locality, through all the changes of the successive seasons. It will avail nothing in support of the popular theory to assume a modification of climate; for to make the water at the same time, in the same place of congenial temperature for both the walrus and hippopotamus, is blowing hot and cold with the same breath in a manner as inconsistent as it really appeared to the honest-minded satyr whom *Æsop*, in one of his fables, represents as indignantly driving a traveler from the shelter of his hut for such reprehensible practice. The elephant and reindeer both feed exclusively on the products of the dry land, but they are the veriest antipodes among the highly organized animals in their constitutional habits, being absolutely confined by their nature to extremely opposite isothermal zones. To bring together extinct species of these extremely different classes of animals, and presume that in former times they may have derived their daily sustenance from the same region, each enduring continually the same degree of heat and cold throughout the year, is in no wise more reasonable than it would be to attempt the same treatment of their living representatives. Such an assumption involves an utter negation of the recognized principles of classification in natural history, and, if successfully maintained, would render nugatory the deductions of the comparative anatomists, whether they be applied to either living or extinct species.

No theory accounting for the origin of the drift deposit has ever been propounded which did not embrace within itself fatal inconsistencies, other than that which ascribes it to the action of a universal deluge; and all the phenomena relating to the sedimentary rocks may be more logically explained on that hypothesis than any other that has been proposed. I have before stated that

## Geologists Meet this Hypothesis

Simply with the assertion of the utter impossibility of such an occurrence. Nevertheless it evidently did happen, and no doubt from causes as easily explained as those which produce an ordinary river flood, if it were only possible that men might be accorded the same facilities for investigation as they have with regard to the latter. In consideration of the fact that these are now known to be meteoric cycles, it is not unreasonable to suppose that there may be cycles of much longer period whereby such a catastrophe as universal deluge might result from some cosmical cause of a nature different from that of the meteoric cycle. But I have neither the capacity nor the inclination to extend speculations backward beyond an observable basis to the incipient stages of world-making. It seems to me ridiculous that the world-making scientists should persist in the promulgation of these absurd theories in the face of Newton's mathematical demonstration of the impossibility of the planets and their satellites having been produced and thrown into their existing orbits by the natural effect of centrifugal force, without the special intervention and direction of some intelligent creative power. It is reasonable to presume that the production of a deluge would be by means of an

## Excessive and Long-Continued Rainfall

Which, of course, would be principally within the tropics. That would produce a rapid flow toward the poles. This flow would bear with it immense numbers of dead bodies of tropical

animals, and uprooted tropical trees, and great quantities of the smaller growths of tropical vegetation. The violent action of the waves and currents would destroy to a considerable extent the surface of the rocks, and re-form in connection with the debris of all pre-existing loose materials. In consequence of its volume, warmth, and rapidity of flow, the tropical waters would melt the ice and penetrate far into the polar regions, still bearing with them a large proportion of their burden of tropical animals and plants.

When the rain had ceased, and the waters had begun to subside, it would be by evaporation, which would principally occur within the tropics. This would produce a reflex of currents from the polar regions. In the meantime the tropical animals and plants, along with the Arctic forms which had been destroyed, would have become incorporated with the polar earth and ice. Detached floes and icebergs containing such remains indiscriminately mingled would be carried much farther toward the equator than ever occurs with similar formations at the present time. As the waters subsided the ice would be stranded on the land surfaces, where, by its melting, the contained animal and vegetable remains would be released and become incorporated with the drift as they are now found. As the waters advance from the tropics certain classes of animals and plants, either in consequence of having originally possessed a small degree of buoyancy, or from having become water-soaked, would become incorporated with the earthy materials which the tropical flow deposited.

In this manner would

#### The Coal Veins

Be formed, and comparatively sparse deposition of certain classes of animal remains in the rocks containing them occur. Before the reflex of waters from the poles transpired the deposition of the tropical currents had become consolidated in the form of stone. That effect might have been produced from chemical causes in a short space of time while it was still covered with water, in a manner similar to that of puzzolana or a conglomerate made with Portland cement. Admitting the occurrence of a deluge such as is described in Genesis, it is not unreasonable to suppose that the immense quantity of tropical animal and vegetable remains now found distributed over the temperate and polar zones might have been transported there by its agency.

Hugh Miller, in his "Cruise of the Betsy," says: "That much of the wood used in building in the smaller and outer islands of the Hebrides

#### Must Have Drifted Across the Atlantic,

Borne eastward and northward by the great Gulf stream," some of it "with roots and branch attached, bearing marks of having been swept to sea by transatlantic rivers. Nuts and seeds of tropical plants are occasionally picked up on the beach. My friend gave me a bean or nut of the *Dolichos urens* or cowitch shrub of the West Indies, which an islander had found on the shore some time in the previous year, and I attach some little interest to it as a curiosity of the same class with the large cones and the fragments of carved wood found floating near the shores of Madeira by the brother-in-law of Columbus, and which, among other pieces of circumstantial evidence, led the great navigator to infer the existence of a Western continent." It is probable that the currents of the ocean, and particularly that great current which issues from the Gulf of Florida, and hence denominated the Gulf stream, aid very much in transporting across the mighty Atlantic these American products.

They are generally quite fresh and entire, and afford additional proof how impervious to moisture and how imperishable nuts and seeds generally are. One of the other "pieces of circumstantial evidence" to which Miller refers as leading to Columbus' discovery of America was the finding the dead body of a man drifted on the Azores, in a condition so well preserved as to show that it did not belong to any race of men known at that time by Europeans. It must have come from America. The Alentian islanders at the present time rely entirely for their supply of timber on driftwood cast upon their shores by the great Japanese current from the tropical coasts of Asia.

In view of these facts the conjecture is quite plausible that at the time of the deluge, when the tropical ocean was covered with the floating carcasses of animals and the wreck of tropical forests, and raging with a swiftness of currents, and swept by a violence of winds unparalleled by any similar phenomena of the present time, they might have been transported in numbers as great and quantities as large as they each appear when their remains are now found. I will now present a fact, which, by fair induction, gives

#### Strong Additional Proof.

In correspondence with others I have stated in confirmation of the conclusion, that not only the drift but the hard surface rock on which it immediately reposes resulted from a cataclysm, and furthermore, that immediately preceding its occurrence the earth on the same parallels of latitude was possessed of a climate identical with that which now prevails.

A few miles below where the canal and locks are now being built at the cascades of the Columbia river and the same side, imbedded in a soft, horizontal stratum of conglomerate, there are several trees varying in size from that of less than one foot to as much as four feet in

diameter. This conglomerate lies between high and low water mark of the river.

It is immediately covered by a hard, dark-colored rock which geologists call basalt, which at that point projects in a shelving manner over the softer conglomerate, in consequence of the latter having been eaten away by the action of the river current. This covering rock here forms the face of the Cascade mountain, rising very abruptly to the height of about one mile. The fossil trees all project endwise, horizontally from the bank. The bodies have been transformed to a compact, black stone; but the bark is so little changed either in texture or color as to render its identity quite certain with that of the grand fir which now greatly predominates in the forest growth of that region. Although some of these trees are separated from the covering rock by a distance of only a few inches, they do not, any of them, give the slightest indication of having ever been subjected to any great degree of heat.

#### If That Great Mass of Rock

Had been deposited on them in such near proximity in a molten state before the trees became petrified or else transformed to charcoal; if it had occurred after they were petrified, the great heat must inevitably have vitrified their entire substance. There is another circumstance of my own knowledge connected with this so-called basalt that proves conclusively that it is not of igneous origin. The same kind of rock as that which covers those fossil trees extends continuously downward to the mouth of the river and upward as far at least as 150 miles; how much farther I do not know, having never visited the country higher than about that distance. About 80 miles above the Cascades, opposite the mouth of a small tributary named John Day's river, in this same basaltic rock where it rises abruptly to the height of fully 1000 feet, there occurs a horizontal stratum of soft, coarse-grained, grayish-colored sandstone, lying a few yards above the river surface. Where the sandstone is in contact with the massive black rock which incloses it, it does not in any manner give indication of having been subjected to great heat.

It certainly would have done so had it been directly covered with so large a mass of molten matter. Geologists who have explored

#### The Valley of the Columbia River

Ascribe all of this extensive-body of black rock to an immense outflow of ancient lava, presumably emanating from the Cascade mountains. I will direct their attention to another objection which probably has hitherto escaped their notice.

On the south side of the Columbia river, in the vicinity of Fifteen Mile creek, between Cascades and Dalles, this so-called basalt presents clear lines of stratification of even thickness, gently inclining toward the heart of the Cascade range; consequently, if they be right, at that point at least, several successive lava flows must have pursued the even tenor of their way "on an uphill grade. I apprehend, however, that they will find little difficulty in properly adjusting their theories to an apparent inconsistency so inconsiderable as this, in a manner satisfactory to themselves, at least after having successfully adapted a universal glacial sheet to the unphilosophical procedure of shoving it—get uphill on the same principle as a man might attempt to lift himself by tugging at his boot straps—from the north polar region over a large portion of the north temperate zone.

#### Neither the Tropical Animals

Whose remains are now found in such great abundance in the polar regions, nor the tropical plants, the remains of which are found in the same locality, could have possibly ever lived or grown there. Astronomers have proved that there never can have been an entire reversal of the poles of the earth, nor ever any considerable change from the position which they now hold in relation to the other celestial bodies of the universe. It is well known that tropical animals and plants at the present time cannot exist nor grow without artificial protection where the days and nights are not of nearly equal length and the temperature of little change during the entire year. Reasoning by analogy we must conclude that it has always been so with the same classes of animals. Regardless of other conditions, it is impossible that there ever could have been any near approach to equality of temperature in a region where the sun was almost continually below it during the other half. But if at some former period the polar regions were, as geologists teach, teeming with tropical animals, and the same regions over-run with tropical vegetation, they must admit that the change from that condition to the succeeding glacial one which they own occurred, could not have been gradual, but must have occurred suddenly, overwhelming everything at one fell stroke, else the bodies of tropical animals would not now be found there, frozen in ice or earth, in a state of almost perfect preservation.

#### I would Here Ask Geologists

If such a catastrophe as that is any more comprehensible or more easily explained by any known law of nature than the occurrence of a universal deluge, which they aver is an impossibility. Prof. Geikie, in his recent work on geology, speaks of the so-called Siberian mammoth as an Arctic animal. He is probably not aware that Humboldt states that fossils of the mammoth exist in the tropical regions of South

America. The statement occurs in one of Humboldt's books entitled "Humboldt on Rocks." Probably Prof. Geikie and other modern geologists regard such books as being of a character too antiquated to be worthy of any attention. By the same rule of logic geologists might class the common Indian elephant with Arctic animals, for I have seen, myself, the tusks of the so-called Siberian mammoth and the tusks of the Indian elephant taken from what was virtually the same bone bed in the Willamette valley of Oregon.

I now propose to prove, by what I consider incontrovertible argument, that the drift formation could not have been produced by glacial action as is now popularly taught. According to the teachings of geologists the animal and vegetable remains now found in the drift must have been of those suddenly overwhelmed at the beginning of the so-called glacial epoch, and consequently must have been lying immediately on the surface of the ground. Now, if it were true that a solid sheet of ice covering the greater portion of the Northern hemisphere accumulated on those remains to a depth of 6000 feet and was, by some means, impelled southward, every vestige of those remains, whether animal or vegetable, must have inevitably, under such conditions, been ground to impalpable powder instead of appearing distributed everywhere in the drift as now found.

(Concluded.)

#### School Experts and Practical Miners.

EDITORS PRESS:—The man who wrote that article in the PRESS recently strikes the keynote of the whole trouble. This business is not understood at all, and there will be no harmony until it is. The practical man is disgusted with science, because he knows that theories do not agree with the facts, and the scientific man curses him because he does not make the facts agree with the theories, and both sides try to make a fool of the printer, which only adds to the confusion. Each should know exactly what to expect of the other, and then we would advance firmly and surely and soon understand far more than we do to-day. I understand the need of a scientific education as well as any man, and feel the need of it as keenly. But my way is to do the best I can with what tools I have on hand, and not fret and stand idle because I cannot possess the whole kit. And if "Joe" has found out something I do not know, I compromise with Joe, rather than make an ass of myself by trying to appear smart about something I do not understand. But perhaps self-importance would rather make a fool of himself before the whole world than to knuckle to "Joe."

"The Old Man of the Mountains" is right. We miners should organize immediately and firmly, and try and save for the country's good what little is left to us. H. CLENDENEN.

THE WILLOW CREEK MINE.—This mine of argentiferous galena, situated on the line of the Virginia & Truckee Railroad, between Washoe City and Steamboat Springs, is still in process of active development by means of the main tunnel run into the hill at the rear of the concentration mill. The tunnel is now in 570 feet, and must soon strike the ledge, 215 feet below the croppings. A considerable proportion of the ore in the ledge is a solid mass of mineral, needing no concentration, and the Frue concentrators are found to be very effective in concentrating the rest; but the low price of silver is rather discouraging at present, all the more so from the fact that the amount of gold in the ore is only three or four per cent. The average percentage of gold in the general ore of the Comstock is about 40 per cent, which is a very material consideration; otherwise the vast amount of low-grade ore now being worked would have to remain in the bowels of the earth. Colonel C. C. Stevenson, the managing power of the mine, however, is, and always has been, one of the most practically enterprising mining men of this State, employing numerous men for many years at regularly established wages, and he proposes putting the Willow Creek mine into the most advantageous shape for economical extraction and reduction of the ore, whether it pays or not.—*Virginia Enterprise*.

TIN SMELTING IN WEST VIRGINIA.—In 1867 a party at Point Pleasant, West Virginia, formed themselves into a joint stock company for the purpose of developing the mineral resources of a large body of land in the Hanna district, Mason county. The matter remained passive until last year, when new life was infused into some of the incorporators, and they put experts to work upon the land. Several tests were made with smelting furnaces, and the reports of the experts confirmed, and arrangements have now been made for the immediate erection of a \$30,000 furnace for smelting the ore.

THE CONTINENTAL AND ENGLISH RAILROADS are beginning to pattern very closely, in their car building, after the most approved American patterns. The demand for the divan of the compartment car is quite strong. It is a system that now finds favor with only a very few of the extreme aristocratic class of travelers. The American plan of dividing off one or two separate apartments is all that is necessary. The American aristocrat, when he chooses to travel "in style," charters an entire car, if he does not happen to own a palatial railway vehicle.

#### Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

TRIGGER ATTACHMENT FOR DOUBLE GUNS.—Chas. E. Burgans, Oakland. No. 344,896. Dated July 6, 1886. The invention relates to an attachment for double-barreled guns having two locks and two triggers, whereby they may be fired independently, and it consists of an intermediate plate with a spring device which operates between the forward trigger and the sear of the lock which it operates, so that after the first barrel has been discharged the forward trigger may be drawn back until the finger engages with the rear trigger so as to fire the other barrel without changing the fingers from one trigger to the other.

DISK SEEDER AND CULTIVATOR.—B. C. Dorsey, Porterville, Cal. No. 344,450. Dated July 6, 1886. This consists in a peculiar wheeled frame, having a seed-box and carrying inclined or angled bars, the outermost ones of which are fixed, and the innermost are automatically adjustable; in two inclined disk-gangs mounted on the inclined bars, the inner or adjacent ends of the disk-gangs being made to overlap; in novel boxes, in which the shafts of the disk-gangs are mounted, and in details of construction. In this machine all the disks of the gangs cut to the same depth; and they are arranged so that there is no uncultivated strip in the center.

AUTOMATIC GAS CUT-OFF.—Chas. Leech, Oakland. No. 344,916. Dated July 6, 1886. The invention relates to that class of devices intended to shut off the flow of gas, when by any accident the flame is blown out and the key is not closed. The invention consists in a metallic wire or strip above the burner-tip, a valve within the burner adapted to find a seat against the base of the tip, and a connection between the valve and the metallic strip above, whereby the expansion and contraction of the latter operates the former to cut off or open the flow of gas. The invention further consists in details of construction relating to the means for mounting the metallic wire or strip, the means for adjusting it, and the means for limiting the movement of the valve and relieving the metallic wire or strip of its weight when lowered. The object of the invention is to provide simple and effective means for cutting off the supply or flow of gas without reference to the ordinary key, so that there shall be no danger in inadvertently or ignorantly blowing out the light.

PROGRESS IN ACCURACY OF LEVELING.—Remarkable accuracy is now attained by engineers in cutting tunnels through mountains, working from both ends. Thus at the Musconetcong tunnel, of the Lehigh Valley Railroad, the alignment tested to 0.04 foot, or less than one-half inch. In this case levels were run over a mountain 5000 feet long and 450 feet above the line; also into the tunnel at each end about 2500 feet to the point where the headings meet. These tested to 0.015 foot, or less than 1-5 inch. The chaining carried by the steel tape measurements over same distance tested, on the headings coming together, to 0.52 foot, or 6.4 inches. This accuracy is, to a large extent, a development of recent years. In the annals of the State of Pennsylvania it is mentioned as a remarkable specimen of accurate leveling that in a circle of 12 miles that was leveled the error was only 1.2 foot. This was in 1824. About 50 years afterward, or in 1878, engineers engaged in running a line of levels between the Chesapeake and Delaware bays, for the purpose of determining the feasibility of a ship canal, testing some new leveling instruments furnished by the Government. A line of test levels was run over ten miles, and the difference of level on the closing bench mark was only 0.005 foot.

ORIGIN OF CARRIAGES.—The oldest carriages used by the ladies of England were called whirlicotes or turning coaches. These became unfashionable after Ann, the daughter of Charles IV and Queen of Richard II, about the end of the 14th century, showed the ladies how gracefully they could ride on a side-saddle. Coaches were first known in England in the year 1530. They were introduced from Germany by the Earl of Arundel. They came into general use among the nobility in the year 1605. The celebrated Duke of Buckingham was the first who rode in a coach and six horses; to ridicule this pomp, the Earl of Northumberland put eight horses to his carriage. Coaches to hire were first established in London in 1625. There were only 20 of them kept at the principal inns. In the year 1637 there were 50 hackney coaches; in 1654 there were 200; in 1694 they were limited to 700, and in 1755 to 800; there are now 1100.

OLD ROMAN LEAD.—While some excavations were recently in progress at Chester, Eng., at a spot formerly occupied by the ancient Romans, a pig of lead was unearthed which bore an inscription showing that it was cast during the fifth consulate of the Emperor Vespasian, which time coincides with our date of A. D. 74. This lead was therefore cast over 1800 years ago. Further discoveries were anticipated.

## TABLE OF CONTENTS.

EDITORIALS.—Temporary Steering Gear; Meadow Lake Again, 65. Passing Events; Prices of Metals; Native Metallic Iron; Our Guests; Drift and Crosscut; Alpine Mines in London, 68. Fire Extinguishing Appliances; Mining Accidents; Refining Coppery Bullion Produced by Amalgamated Tailings, 69.

ILLUSTRATIONS.—Sloan's Device for Temporary Steering Vessels, 65. Section of Dissolving Tub, 69. CORRESPONDENCE.—Gold Produced and Saved by Electricity; Optimism of Miners; Common Sense Geology, 66. School Experts and Practical Miners, 67.

MECHANICAL PROGRESS.—Improvement in Smelting Iron Sands; How Iron Breaks; The Heating Properties of Exhaust Steam; Future Supply of Iron Ore; Balancing Pulleys; Tests for Lubricants, 70.

SCIENTIFIC PROGRESS.—How Rain is Produced; Colors of the Ancients; Profits of Electric Lighting; Hot Water from Artesian Wells; Influence of Temperature on the Strength of Iron and Steel; The Waste of Life, 70.

USEFUL INFORMATION.—Foaming and Priming; Life's Decay; Pianos in Winter; All Paner; How to Keep Moths Out of Carriages; The First Watch; Natural Gas as Fuel for Locomotives; An Ancient Stone Plow; Gasoline as Forge Fuel; Ivy and Dampness; A Good Paint; Frozen Milk in Fever, 71.

GOOD HEALTH.—Pasteur's Method of Vaccination; Sunstrokes; The Philosophy of Vaccination, 71.

MISCELLANEOUS.—Notices of Recent Patents, 67. Washington Territory Mines, 71.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, Idaho, Utah, Colorado, Oregon, Washington, New Mexico, 72-73.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 76.

## Business Announcements.

Dividend Notice—Paradise Valley Mining Co.  
 Draughtsman—W. H. Smyth.  
 Miss Bisbee's School—Oakland, Cal.  
 Pumps—Dow Steam Pump Works.

## Passing Events.

This week has seen the arrival of thousands of visitors from the East and interior, to take part in the festivities of the Grand Army of the Republic, which take place in this city during the whole of next week.

The region along the Carson & Colorado railroad, Nevada, is showing evident signs of mining advancement, and several of the districts will in time become very prosperous. In San Diego county, in this State, the mines once abandoned are again producing bullion and paying good profits.

Good news comes from Alaska mining regions, and capitalists are now examining other mines on Douglas island with a view of opening them and putting up extensive reduction works.

The Legislature is still in session and discussing the irrigation question, but no decisive action has yet been taken.

## Drift and Crosscut.

In a recent article we remarked on the difference between "a shoot of ore" and an "ore-chute," terms which are very frequently mixed up badly in descriptions of mining property, and often by men who ought to know better. Two other mining terms often used in a confusing manner are those of "drift" and "crosscut," the distinction being seemingly unknown to many. The stratification of the country rock may strike north and south, for instance, as clearly as the ore bodies themselves, yet a crosscut through it will be called a drift just as much as an excavation on line of the ore body

itself. The late Joseph Wasson well explained the difference several years ago in saying: The average miner will apply the word crosscut merely to a cut across the ore body itself, from wall to wall, no more; everything beyond that, however much it may run crosswise of the country rock, is designated a drift. Webster, as well as the mining dictionaries of any thoroughness, defines the word drift "to follow a vein." "To drift with the current" is a natural expression outside of mining; and an ore body is but another word for current; its walls answer to the banks of a stream. Crosscutting in mining is but searching for another stream, channel, branch, etc.; drifting in mining is but following the current of the stream when once found.

In the glossary of mining and metallurgical terms compiled by R. W. Raymond, Ph. D., Secretary of the American Institute of Mining Engineers, which as an enlargement and revision of that prepared many years since by Chas. G. Yale, editor of the MINING AND SCIENTIFIC PRESS, for Gregory Yale's work on "Mining Claims and Water Rights in California," the term "crosscut" is thus defined: 1. A level driven directly across the course of a vein. 2. At an angle with the grain of coal. The word "drift" is defined: 1. A horizontal passage underground. A drift follows the vein, as distinguished from a crosscut, which intersects it, or a level or gallery which may do either. 2. The unstratified deluvium resulting from glaciers or icebergs.

## Prices of Metals.

The downward tendency of silver is most discouraging to silver miners. It has now reached the lowest point ever recorded, and does not seem to have stopped yet. London advices advance the opinion that the decline is caused by an unsettled feeling regarding the policy of the new Government toward India, and its action regarding the China and Burmah difficulty. The question of the decennial presents formerly paid to China by Burmah is still unsettled, and manifestations of Chinese sympathy for the Dacoits in Burmah are growing daily more direct, and a large number of Black Flags have joined the Burmese rebels. The Viceroy of India asks for the prompt rearming of the artillery and infantry. The native organs oppose this kind of expenditure and point with justice to oppressive taxation and undoubted misery of the poorer classes, the serious condition of the land question and the numberless social problems which remain unsettled and untouched. It is believed the Government will not parley with the military necessities, and as the arms of India are absolutely inefficient the Government will have them replaced without further ado at India's expense. It is feared that the influence of Churchill will widen the breach between China and England and increase political agitation in India that will probably result in insurrection; hence the little or no demand for Eastern exchange and the reduced bids for council bills. Whether this is really the cause or not, the fact remains that silver is so low that the discount from par value is very damaging to silver-mining interests. Though quoted at 94 cents, 93 is as much as is bid in this city, and the metal is so demoralized that dealers do not know what to do. A year ago silver was \$1.08.

Copper has been for a long time very low, and several large copper mines in this country have had to close down for the time being until prices improve. Heavy supplies are the cause of this low price, together with slackness of legitimate—not speculative—demand.

Iron has been in a bad way for a long time, and a good many works have remained shut down in this country and England during the past half year. On this coast the Clipper Gap mine has shut down permanently, and the Oswego works, Oregon, are also closed.

Antimony has continued dull and prices have fallen lower and lower. Borax, of which this coast produces large quantities, does not bring anything like the price it did a few years since. Lead, though somewhat higher than last year, is not high enough to make the lead miners very happy. Tin and quicksilver are the only two metals showing an upward tendency. Quicksilver has gone up of late owing to low stocks, small product and pretty good demand. In tin there is a good business being done, with improved prices.

On this coast the prices of silver, lead and

copper are the most important to us. Within the past few years many copper mines have been opened, and now many more would be worked should prices of product warrant. The depression in the other metals, however, has given an impetus to gold-quartz mining from which this State, as the leading gold-producer, is profiting.

## The G. A. R. Encampment.

The Twentieth National Encampment of the Grand Army of the Republic will convene August 3d, in San Francisco, and continue in session for a week. It will probably be the most interesting and brilliant affair of the kind ever witnessed on the continent. Already the advance guard is arriving and the hotels are lively. A train of 28 Pullman cars is on the road, crowded with Boston veterans and their wives. From the latest advices, in a few days more there will be not less than 30,000 Grand Army visitors among us. They are coming from all parts of the Union—Maine with its six months of winter, Minnesota and Kansas with their frosts and blizzards, and Kentucky and Tennessee, the land of big-boned men, lots of children, cornpone and hominy. They are coming with great brass bands, big drums and fifes, and will make the air sonorous with the best of martial music. The female drum corps from Minnesota will be a novel feature. Those frisky old fellows, the Veteran Corps of Elizabeth, New Jersey, propose to parade in a different uniform on each of the six days of the Encampment. Many of the Sir Knights of De Molay Commandery, Louisville, who carried off the first trophy at the Templar Conclave of 1883, are coming back to see us as soldiers of the Grand Army.

They are welcome, thrice welcome, these valiant men who bore aloft the flag through that terrible war. They will find San Francisco gorgeous as a tropical forest, its streets one long emblazonry of military symbols and devices. The bare and gloomy walls of Mechanics' Pavilion will blossom into banners, pendants, badges, battle-pieces and historic memories. Merchants, shop-keepers and householders will vie with each other in welcoming them by their magnificent display of decorative art and other ways. Even old Mammon will get a sniff of patriotism and put on his best clothes for a holiday.

The grand march and grand camp-fire will be the chief features of the program. The march will be along streets profusely decorated with the national colors, and under an arch 80 feet high surmounted by a monster eagle, 30 feet from wing tip to tip, and ornamented with the figures of General Grant and Admiral Farragut, and of Presidents Washington and Lincoln. Our visitors will not make as showy a pageant as the Knights Templar; but they are no kid-glove soldiers. They are men who have smelt powder, worked in the damp trenches, toiled in the weary marches, and fed on hard-tack, beans and glory. San Francisco will put its best foot forward to make the days of our gallant visitors pass enjoyably, and Oakland, Sacramento, San Jose, Los Angeles and other places are making elaborate preparations to give them a reception. The fact is, there is a deep-laid plot, a deliberate conspiracy, to lure away these Grand Army folks into the country, feed them on climate, and capture as many of them as possible and hold them willing prisoners in the land of the orange and vine.

## Native Metallic Iron.

[Written for the Press by ARTHUR F. PRICE, F. C. S.]

The presence of native iron in rocks of terrestrial origin has been seriously doubted by many leading scientists. This occurrence of the metal is well known in aerolites, which are, however, of celestial origin, and contain the iron associated with other metals.

I have recently received from Arizona a piece of rock containing metallic iron in flat scales and rounded lumps, and in such quantities as to settle beyond dispute the fact that iron does occur native in rocks which are undoubtedly of terrestrial origin.

The composition of the rock containing this iron, as analyzed in the metallurgical establishment with which I am connected, is: Silicate of alumina, silicate of magnesia and oxide of iron, the last doubtless resulting from the oxidation of the metallic iron. The metallic iron contained amounted to over 7 per cent.

## Alpine Mines in London.

We have just been reading in a London paper one of those fine mining prospectuses which the English agents get up when they are floating a company. In this sort of thing our cousins across the water greatly excel us. They can really promise more from a mining venture than we can, which is saying a great deal. In this case the company is called the "Nevada Consolidated, limited," because the mines are in California, and have nothing to do with Nevada, though the mines are described as 45 miles from the Comstock, Nev. The group of mines is stated to contain "nearly five miles of gold and silver-bearing lodes." There are three groups—the Colorado and Advance, the Sauquet, and the Marian. The prospectus says: "These lodes possess the characteristics of true fissure veins, and in the Colorado No. 2, on which the principal work has been done, the ore is met with in masses, similar to those which formed the great bonanzas of the Comstock mine. Soft ore from these masses is worth \$1000 to \$1500 per ton of 2000 pounds, and by simply washing the clay, the sulphurets and free gold left have yielded as much as \$3000 per ton."

Mr. Ottokar Hoffman is quoted as saying the formation is similar to that of the famous Trinidad mine, in Mexico, and Silver King, in Arizona. The average value of the ore is \$230.84 gold and \$333.19 silver, or \$564.03 per ton.

"On the Advance mine a two-compartment shaft has been sunk 320 feet, being 396 feet below the lowest tunnel in Colorado No. 2. This shaft is provided with a good set of hoisting and pumping machinery, and from it it is proposed to work the mines at a greater depth than can be reached by the present levels. Upon the Sauquet portion of the property a double-track tunnel has been driven 1400 feet, intended to develop this group of lodes, measuring 11,000 feet in length, and all of them promising, from assays which have been made, good results in gold and silver. This tunnel strikes the various lodes which are parallel to each other at depths varying from 715 to 2060 feet, and when completed will be 6200 feet long. All lodes which it may intersect in its course belong to the company over and above those shown on the plans. There are on Colorado No. 2, a 20-stamp mill, chlorination works, bullion furnaces, and all necessary appliances, so that the company can immediately commence work; and returns of bullion can be made within three months thereafter. The ore being of a soft nature, the 20-stamp mill can crush 50 tons per day, giving two tons of concentrations, worth, according to Mr. Hoffman, \$564 per ton, less mining and milling \$5 per ton, or \$250, leaving a net daily profit of \$870, amounting (for 300 days' work) to \$261,000 or £52,000 net per annum.

"The above amount may be more than doubled by increasing the number of stamps, the erection of which will be immediately proceeded with; so that a sum of over £100,000 per annum should be available for dividends from Colorado No. 2 alone."

The capital of this company is £400,000 in 400,000 shares, and it is stated that \$500,000 has been subscribed. The purchase price is £300,000, or about one million and a half dollars, to be paid entirely in shares. Returns of bullion are promised in three months; and the Colorado No. 1 is stated to be alone capable of yielding \$500,000 a year.

Some of these mines have produced bullion in times past, and may do so again; but they have no specially great reputation in California; and the estimated profits, as given above, if at all likely to be realized, ought to have made the owners hold on to the mines themselves and not sell for stock. Mining in Alpine county in this State has not produced any very remarkable results thus far, unless it has been in the line of expenditures. It seems strange, when the mines are opened as described, and have chlorination works, mills, and all appliances, ready to produce bullion in three months, they were not worked at once by the owners. To say the least, if they needed any money to start, and any such showing as this prospectus gives could have been legitimately made, they would have had no difficulty in getting it here at home.

GOLD quartz crushing has been resumed in the old Meadow Lake district, Nevada county, by a new process.

## Fire-extinguishing Appliances.

The Fire Commissioners of this city have asked the Supervisors for permission to purchase two more fire-engines. It is high time this should be done. The several large fires which have occurred in this city in the past few months have shown that our local department is deficient in apparatus. The organization has not grown as rapidly as the city has. There are only 15 engines, and not half enough full-paid men. The city is now large enough for a complete metropolitan system with all the men in full pay, having nothing to do but attend to fires. As it is, the majority now follow other occupations, and are not regularly at the enginehouses where they can ride to fires. Wherever they are at work they have to run to the fire, and often arrive there in an exhausted condition. For a large city like this, where there are so many wooden structures and high winds prevail, the plan is crude and unsatisfactory.

South of Market street, in the section where the great foundries and large mills are, there is not a single engine. Moreover, the wholesale trade is moving that way and fine large structures are going up. One of the new engines, which it is proposed to buy, ought to be stationed in that region so as to be near at hand in case of fire. Moreover, the department ought to own a water-tower, by means of which the combined streams of several engines could be thrown on high buildings. It should also own a chemical engine for extinguishing incipient fires in buildings, where water would do great injury to valuable goods. Some of the light cotton hose in use in Eastern cities should also be procured for use in high buildings. Its lightness admits of its being carried up-stairs more readily than the heavy hose in use.

Eastern cities are much better provided with fire apparatus, in proportion to population, than our own; and it is false economy to deprive our department of any advantages that may be derived from improved appliances. We are much behind the times in this respect. Our department is composed of brave and efficient men, skilled in their work, and no one can find fault with their efforts. But the force should be stronger and the appliances increased. In the last six months the property burnt amounted to \$1,395,217; insurance, \$510,312; unpaid loss, \$884,904. This shows that citizens have as much at stake as underwriters. With a more completely equipped fire department there would be much less liability of loss.

## Mining Accidents.

A serious accident occurred last week at the Kennedy mine, Amador county. A miner named Nicola Gerceit had been sent to fix a chain across the shaft, at a point about 110 feet from the bottom. The skip was about 10 feet above him. After fastening the chain, and before he had time to get out of the way, the skip came down upon him, crushing him across the abdomen and breaking the left leg between the knee and ankle. Notwithstanding his injuries, he managed to hold himself in his position by catching hold of something in the shaft until extricated.

A fatal accident occurred at the Lane mine, Angels, Calaveras county, on Wednesday of last week, caused by the bursting of the mud drum in the furnace. At first it was believed that the boiler had exploded, but as soon as the smoke, dust and steam lifted itself from the horrifying scene it was discovered that the mud drum in the furnace had exploded, but through what cause is unknown. The engine was considerably smashed, the building partly unroofed and the front and sides blown out; the masonry work of the furnace was thrown in heaps all over the premises, being blown completely to atoms. The machinery was not in motion at the time of the accident, having been shut down but a few moments previous. Mr. James Lane, brother of Charles Lane, one of the principal owners and superintendent of the mine, was in charge of the engine at the time of the accident and was in the furnace-room at the time of the explosion. As soon as access to the furnace-room was considered safe the mill men hastened to the assistance of Mr. James Lane, whom they found struggling in the throes of agony, frightfully scalded and bruised and partially buried beneath the hot rocks of the furnace. The unfortunate man died soon after.

## Refining Coppery Bullion Produced by Amalgamating Tailings.\*

NUMBER 3.

## Roasting White Bullion.

A charge was generally about 300 pounds, the actual amount being determined at any time by the quantity on hand, the furnace being treated as much as 400 pounds.

The sulphurized material roasted quite easily, and no special difficulties were experienced in working up to a certain degree of excellence. But it seemed practically impossible to sulphurize all the silver, or to prevent the formation of a very large percentage of lumps. No matter how gently the temperature was raised, or how diligently the material was rabled and pounded, the mass was in the beginning so shaky that almost the same proportion of lumps were found at the end of the operation as when the process was conducted more hurriedly.

The fire was increased gradually from the beginning, but the furnace was at no time very hot. For some two hours the charge was stirred constantly and vigorously, to expose all parts equally to the heat, and to prevent the formation of lumps, or to crush up those already formed as much as possible. About three hours after the roasting had fairly commenced,

Several times, perhaps a dozen or even more, when, according to the tests, the charge had passed through the condition of maximum sulphatization of the silver; and, beyond this, so that the silver sulphate had been decomposed to a large extent, that is, the tests had yielded decreasing amounts of chloride, by continued hot firing the charge has been brought back to its usual proportion of silver sulphate; that is, the tests have shown an amount of chloride gradually increasing up to the usual point. For instance, when a charge has been ready for drawing at 1 or 2 o'clock P. M., but has remained in the furnace until, say 4 o'clock, the tests at this last hour show very little sulphate, but by firing strongly and stirring the charge with moderate vigor, the amount is increased according to tests, until about 6 o'clock, the average proportion of silver sulphate, so far as the eye can judge, is again reached.

## Dissolving.

The roasted bullion passed next to the bluestone works, where it was treated with hot dilute sulphuric acid (chamber acid), the base and white being manipulated separately (as a rule), but in exactly the same manner. This state of affairs was brought about commonly by some accident; for instance, my detention from the furnace at the time for making tests. But I have also caused it deliberately, although

SECTION OF DISSOLVING TUB.

the first test was made of the condition of the silver. The test consisted simply in putting a small quantity of the hot charge into a porcelain saucer, partially filled with water, and adding a dilute salt-solution. The color of the solution, the appearance of the charge and the relative quantity of silver chloride formed, show the condition of affairs. The eye is soon trained by experience. The "spangle-reaction," mentioned by Prof. Eggleston, in his paper on the "Boston and Colorado Smelting Works," that is, the reduction of the sulphate to bright, glittering spangles of metallic silver by suboxide of copper, was often seen in great beauty.

When the sulphate of copper was almost entirely or even quite decomposed, that is, the test solutions had become nearly or quite colorless, the amount of sulphate of silver (or of chloride in the test) was at its maximum, and the charge was drawn. When the roaster lighted his fire in a cold furnace at 7 A. M., the charge was usually out of the furnace about 2 P. M. If the furnace was warm in the beginning, the time was often reduced materially.

As before mentioned, it seemed impossible to get all the silver into the state of sulphate. The highest proportion ever noted was 75 per cent, while the yearly average attained was about 60 per cent.

The roasting process was conducted essentially according to the directions given in the text-books, and in its action conformed to the descriptions given. But, at times,

## A Phenomenon was Observed,

Which, as far as I have been able to learn, has not been described before in print.

\*Read before the American Institute of Mining Engineers by A. D. Hodges, Jr.

with fear and trembling each time.

Mr. C. A. Stetefeldt has suggested to me a possible explanation of the apparent regeneration of the sulphate of silver in the over-roasted charges. At the Mansfield Works, in Germany, the roasted copper matte in the Ziervogel-process is leached first with pure water and then with water acidified with sulphuric acid. This, it was said, favors the solution of sulphate of silver, a part of which may be present as a basic salt insoluble in pure water. While the text-books on chemistry do not record the existence of a basic silver-sulphate, there are indications that such a salt occurs; and it would seem very possible that, in over-roasting the sulphurized bullion at Dayton, the common sulphate was partially decomposed to a basic sulphate, and this, in turn, on continued treatment, was changed back to the ordinary sulphate through the action of the sulphides in the undecomposed lumps, a comparatively small quantity of sulphuric acid being required to effect the regeneration.

The original charge in the furnace consisted, in round figures, of about 500 parts silver, 500 parts copper and 17 parts sulphur, with very small amounts of gold and of iron. I am not aware of the presence of any other metals.

The roasted bullion was sifted through a No. 8 wire screen. The average amount of lumps in 1876 was 17 1/2 per cent of the original charge. I have no notes showing anything as to the percentage of lumps from overworked charges. The highest amount ever recorded was 22.3 per cent. The lumps contained copper oxides, copper and silver sulphates and copper and silver sulphides principally. By vigorous manipulation a considerable part could be rubbed through the screen, but this was not permitted.

When possible, the lumps were allowed to accumulate, until amounting to enough for a furnace charge, when (after crushing) they were roasted by themselves, the operation requiring only two or three hours.

The dissolving tubs, shown in the cut on this page, are six feet in diameter and four feet deep, clear dimensions. The sides are composed of 45 staves, three by six inches, and four feet six inches long, dressed to the proper shape and hooped with three iron bands three-eighths inch thick by two and a quarter inches wide, provided with angle irons. The bottom planks are 3x12 inches, the lumber dapped into sides, with two cross-pieces, 2x12 inches, nailed below them.

The bottom of the tubs and sides, for a height of 12 inches above the bottom are lined with 14-pound lead, the rest of the sides with 8-pound lead. Directly under the steam pipe in the center of the tub, a piece of 16-pound lead, two feet in diameter, is laid on the bottom lining, and "burned" to it as a protection in case the steam pipe should blow out. A strip of old lead is bent over the upper edges of the sides to protect the lining against the wear of the paddles.

The steam pipe is three-quarter inch AA lead pipe, soldered to iron pipe above the level of the tub. It is closed at its lower end, which reaches within a few inches of the tub bottom, but has four holes bored in its sides, near the end, so that the steam issues in a horizontal direction, instead of impinging vertically on the lead. The steam-pipe is stiffened by clamping to a central timber, two by four inches, hung from and braced to the ceiling, and lined with 8-pound lead where in contact with the bath. Water and acid pipes are provided.

The normal charge was 1200 pounds base, or 1000 pounds white bullion; but the common charge was 1000 pounds of base, or 800 pounds of white. The amounts were regulated by the exigencies of the occasion.

The amount of acid used could not be limited to the exact theoretical quantity requisite to form  $Cu_2O$ ,  $S_2O_3$ , although the men on the tubs were kept within certain limits. For instance, in treating 1000 pounds of material assaying 75 per cent, theoretically 2083.4 pounds of acid, 45° Beaume, would be requisite; this corresponded exactly to 11 1/2 inches in depth of the acid tank. In order to be sure of dissolving out all the copper (and iron), and because a moderate excess of acid did no special harm, being utilized afterward in dissolving ore charges, and as some metallic silver was always dissolved, the men were allowed to use one inch more, or 8.7 per cent. Any amount beyond this limit caused an investigation.

Again, in leaching the charges and in other operations extra acid is necessarily used, at the lowest figures over 10 per cent. Moreover, accidents seem practically unavoidable at times.

The result in practice was that, instead of only 2.8 pounds of 45° acid being used for each pound of metallic copper, an average of nearly 3.7 pounds was purchased by the refinery at Dayton during the year 1876. An unknown proportion of this excess was regained in the other department of the bluestone works, but no allowance was made in the books.

The acid was measured out of a tank whose contents were known. The measuring was by twentieths of an inch. A table was prepared for the men, showing how many inches of each degree of strength were necessary for 100 pounds of charges of given percentage in copper. Two men were employed at each tub.

A COMPANY with an authorized capital of \$2,000,000 has incorporated in Los Angeles for the purpose of boring for gas and petroleum and dealing in the same in Los Angeles county. The company has purchased a tract of land on the west side of the city limits, between Pico and Ninth streets, near the gas wells, and will go to work promptly in sinking wells. There is plenty of gas in that locality to burn for fuel in the engine used for drilling.

THE temporary dam at the mouth of the Big Bend tunnel is nearly completed, and as soon as finished, the water of the river will be turned into the tunnel and work commenced on the permanent dam.

SEVERAL thousand men are wanted at good wages to work on railroad construction in British Columbia.

## MECHANICAL PROGRESS.

## Improvement in Smelting Iron Sands.

Many attempts have been made, during the last few years, to utilize the magnetic iron sand which occurs in immense deposits along ocean shores. It is found in greater or less quantities along the Pacific Coast from Oregon to this city, and still farther south. Experiments have been made in this city to utilize this finely-divided iron ore—the most valuable form in which it ever occurs, so far as the iron product obtained from it is concerned, but hitherto with no practical results. This sand or ore is found, perhaps, in the greatest abundance on the coast of New Zealand, where the most persistent experiments have been made, on a large scale, for its utilization—experiments which have, with these and with New Zealand sands transported to Europe, been of quite practical utility. But we now learn, through the *Auckland Star*, that a still newer and more practical method has recently been discovered by Mr. James Kelly, of Auckland, to which the *Star* refers as follows: The course hitherto pursued by himself and other experimenters has been to extract the magnetic iron instead of uniting the two. Mr. Kelly came to the conclusion that the wrong course had been adopted, and at once instituted a series of experiments with a view to discovering a suitable fluxing material in order to unite the two. After trying many things, Mr. Kelly, having noticed that if common scoria ash got in the furnace it melted at a low temperature, decided to utilize that article. The experiment was accordingly tried, and the result was highly satisfactory. Scoria melts at a comparatively low temperature, and this has the effect of preventing the iron from oxidizing. It is well known that hitherto the oxidation of the iron has been an insurmountable obstacle in the way of the successful smelting of iron sand. It is Mr. Kelly's intention to try experiments with the iron sand in a large way, as he is confident that iron can be produced in large quantities, equal to ordinary pig iron, at a less cost than that of the imported article. Mr. Kelly has patented his discovery.

## How Iron Breaks.

Hundreds of existing railway bridges which carry 20 trains a day with perfect safety would break down quickly under 20 trains an hour. This fact was forced on my attention nearly 20 years ago by the fracture of a number of iron girders of ordinary strength under a five-minute train service. Similarly, when in New York last year, I noticed, on the case of some hundred of girders in the elevated railway, that the alternate thrust and pull on the central diagonals from trains passing every two or three minutes had developed weaknesses which necessitated the bars being replaced by stronger ones after very short service. Something the same thing had to be done recently with a bridge over the river Trent, but the train service being small, the life of the bars was measured by years instead of months. If ships were always among great waves, the number going to the bottom would be largely increased. It appears natural enough to every one that a piece even of the toughest wire should be quickly broken if bent backward and forward to a sharp angle; but perhaps only to locomotive and marine engineers does it appear equally natural that the same result would follow in time if the bending were so small as to be quite imperceptible to the eye. A locomotive crank axle bends but 1-84 inch, and a straight driving axle a still smaller amount, under the heaviest bending stresses to which they are subject, and yet their life is limited. During the year 1883 one iron axle in 50 broke in running, and one in 15 was renewed in consequence of defects. Taking iron and steel axles together, the number then in use on the railways of the United Kingdom was 14,848, and of those, 911 required renewal during the year. Similarly, during the past three years, no less than 228 ocean steamers were disabled by broken shafts, the average safe life of which is said to be about three or four years. Experience has proven that a very moderate stress, alternating from tension to compression, if repeated about 100,000,000 times, will cause fracture as surely as a bending to an angle repeated only ten times.—*Power and Transmission.*

## The Heating Properties of Exhaust Steam.

There has been more or less written and claimed about the use of exhaust steam for heating, some going so far as to say that it is equal to live steam for that purpose. In claiming this they have not analyzed the subject, nor ascertained the heat left in the exhaust, or what is possible to be got out of it. In some places great gains are claimed by taking out condensing engines, replacing them with engines running under a large amount of back pressure and using exhaust for heating. In doing this they have not taken into account the entirely different conditions or stopped to inquire whether they were getting the best possible results from their live steam. Let us see first what is possible from the exhaust. We can

find this from an indicator diagram. We should remember that this is a diagram of work and shows the average pressure that was required to perform that work, and the terminal pressure shows the steam that is thrown away and is useless for further work in that cylinder. It shows only what heat exists in the form of steam, and does not give any account of the condensation in pipes, or cylinder, or amount used in performing work. If we find from test that we are using 30 pounds of water delivered to boiler per hour per horse-power, and we use all the steam for heating, we have the full amount of heat leaving the boiler minus the heat radiated from the pipe. I use it in an engine first. We will probably find, with a good engine, 22 pounds accounted for by indicator, which will be available for heating purposes, which shows a loss of 27 per cent, which is accounted for as follows: The heat from 2.65 pounds of water will be absorbed in work; 33,000-foot pounds per minute or 1,980,000 per hour is one-horse power; and as 772-foot pounds equals one heat unit, 1,980,000 divided by 772 equals 2564.76 heat units, and 2564.76 divided by 966, the heat of vaporization of one pound, equals 2.65 pounds of water which has been actually converted into mechanical work, and the 22 pounds accounted for by indicator plus 2.65 equals 24.65, leaving 30 minus 24.65 equals 5.35 pounds of water condensed in pipes and cylinder and carried over with the steam from boiler. It is evident, therefore, that we have but 22 pounds of water or 73 per cent that leaves the boilers, that is available for steam-heating after the steam has left the engine, and with other circumstances the same, it is possible to do but 73 per cent of the work that live steam will do. After leaving the engine, however, larger pipes must be used than for live steam, and if equally well covered the loss from condensation will still be greater in the large pipes.—*Corr. Boston Journal of Commerce.*

**FUTURE SUPPLY OF IRON ORE.**—Dr. Percy, president of the British Iron and Steel Institute, recently delivered a very interesting address before that body, in the course of which he said: "The future of our supplies of iron ore is a subject of no small interest to members of the institute. The Bilbao and other fine ores are being rapidly exhausted, and it is predicted that such exhaustion is not far distant. Our secretary tells me that he has been informed by an American gentleman thoroughly acquainted with the iron and steel trades, who has been scouring the world in search of suitable ores, that, in his opinion, such ores before very long are likely to become scarce, and consequently to fetch a higher price than at present. This is a somewhat startling announcement. But there are doubtless many unexplored localities in which it is probable good ore will be discovered. The cost of transit, however, and the other local circumstances, may, in some cases, render the ore unworkable on the ground of economy. I may mention a fact which my friend Mr. Bauerman has communicated to me—namely, that in recently visiting South America, he saw in one locality enormous deposits of fine hematite, which extended over a long range. These deposits are as yet untouched, and access to the coast would be very expensive in the absence of roads, as is the case at present."

**BALANCING PULLEYS.**—A correspondent of the *American Machinist* writes that paper: "Supposing the pulley is to be put in good 'standing balance' only. If no spirit level is at hand, the balancing bars may be roughly tested by laying the mandrel on the center; and if it rolls with the same apparent ease in either direction we know the bars are about level. After placing the pulley on, hold it still for an instant and let go, but instead of letting it roll back and forth until it stops, check it a little until you get the oscillations down to about four inches travel of the rim; hold your chalk in readiness, and as it rolls toward the right and stops, dash a small mark on the edge of the rim plumb over the center; as it returns to the opposite stopping point, mark as before. Make a central mark between these two and you have the light spot. Now attach the weights and test it by rolling down to a position horizontal to the center and let go. If it stands still roll it to the opposite side, and if it will stand here also it is correct, but if it rolls down, the bars are low at the end. If you are using cast weights, and find that of two sizes, between which there is very little difference, one is too light while the other is too heavy, give the preference to the light one, as it makes the pulley nearer in balance when running."

**TESTS FOR LUBRICANTS.**—The manager of any mill may, at very little expense, determine for himself all the conditions of safety and economy in lubricants as indicated by the standard of heat developed upon any given shaft. The apparatus required for this purpose is merely a thin brass tube closed at the lower end and two thermometers. The method of using this apparatus is as follows: Place enough water in the tube so that the bulb of the thermometer will be immersed; insert the tube in one of the holes in the cap of the journal, so that the lower end of the tube will be in actual contact with the shaft; hang the other thermometer free alongside; then gauge the relative heat developed with oils and with greases. Each man may thus satisfy himself as to which is best and safest.

## SCIENTIFIC PROGRESS.

## How Rain Is Produced.

Did it ever occur to the reader that there is just as much water in the air above him on a clear, bright day as on a cloudy or rainy one? Rain does not come from somewhere else, nor is it wafted over you by the wind from elsewhere. The water that was over you is simply waited on to some other place. Water is absorbed in the air above us at a certain temperature, and it becomes insensible. Cool that air by a wind draft of cooler atmosphere, or by electrical or chemical influences, and the moment the air becomes cooler it gives up some of the watery particles that were insensible or invisible at the higher temperature. These small particles thus given out unite, and when enough of them coalesce, obstruct the light and show as clouds. When enough of them unite to be too heavy to float in the air, they begin to descend; pair after pair of them come together until a rain-drop is formed. One of these minute rain-drops is made up of millions of infinitely small watery particles.

Air passing over the cold tops of mountains is cooled down so that it gives up a good deal of the concealed watery vapor, and hence little rain falls in the region along the ice side of such mountains. This is why so little rain falls in Colorado, and in other places north and south of that State. The prevailing winds blow from the west, and the cool tops of the Rocky mountains lower their temperature, and thus take out the moisture that would otherwise fall in rain.

## How Rain Drops, Hail and Snow are Formed.

In a paper on "The Formation of Rain, Hail and Snow," recently read before the Meteorological Society, by Mr. A. W. Clayton, F. G. S., the author points out that all observations tend to show that, except under quite abnormal conditions, the temperature of the atmosphere falls as the height above sea level increases; and there seems no reason whatever for assuming that the law does not apply to that portion of the atmosphere which forms a cloud. Hence, if a drop were to be formed at or near the upper surface of a cloud, it would fall down into a region saturated with vapor at a temperature above its own. The result will be further condensation producing a larger drop; and this process will continue until it leaves the cloud. If its temperature be below the dew point of the air it falls through, condensation will continue until it reaches the ground. However, it is obvious that this subsequent gain cannot bear any very large proportion to the growth while falling through the saturated cloud, from which the conclusion follows that the size of the drop must increase with the thickness of the cloud. The author suggests that condensation begins on the upper surface of the cloud by the cooling of some of the liquid cloud particles. If this particle is cold enough it will solidify, and snow will be formed. Should it not be quite cold enough to solidify at once, owing to its minuteness, but remain still below the freezing point, hail is formed. Finally, if the temperature is not low enough for either snow or hail, rain is produced.

## Colors of the Ancients.

Layard says that the colors which have revealed themselves during the excavations at Nineveh display sufficient evidence that they are not inferior to those of the ancient Egyptians, either in number, variety or brilliancy. Instead of the common earthy bole or reddish of the latter people, the Assyrians have left us a color almost equal to vermilion itself. The monochrome pictures which represented the Chaldeans on the wall (Ezekiel xxiii, 14) are said by Gesenius, the Septuagint, and the Vulgate, to have been painted with sinoper or rubrica, a native earthy oxide, like Indian red, while both the great English versions of the Bible now in use, as well as the rabbis, translate the word at issue ("shashar," Jeremiah xxii, 14) vermilion.

At Khorsabad it appears that the red approached in hue to that brilliant color, while the sculptures at Nimroud exhibited a bright crimson or lake tint. Layard thinks there is no doubt of their having made great use of vegetable colors, the materials for which are so plentiful in the vicinity of Nineveh. The rapid evanescence of some specimens of blue and red on plaster, which were bright and perfect in color when first exposed, would appear to favor a vegetable origin, as no susceptibility of the kind is known to characterize any mineral reds or blues with which we are at present acquainted. Layard claims for the older Assyrian period the same colors which have been attributed to the early times of the Egyptians, viz., blue, red, yellow, black and white. He also speaks of a green on the earlier monuments of Nimroud, and of green, purple, violet, brown, etc., enameled in paintings of figures on bricks at the northwest palace.

In allusion to the analysis of Sir Gardner Wilkinson's specimens of the Alexandrian blue, by Dr. Ure, Layard conjectures that the coloring principle may be the same, but affirms that the Assyrian blue is much brighter. He concludes that the color was derived from copper, as he found an old mine of that ore in the neighborhood of Nineveh. Layard considers the

greens of Assyria to be similar to those of Egypt, which are in many instances composed of iron ochre and copper blue. The yellows and blacks he conceives to resemble those from Egypt; and as specimens of the latter class of pigments he mentions calcined bone and black iron ochre. The whites are of alabaster and gypsum. At Khorsabad, the French antiquarian, M. Potta, found green, red, black, white, yellow and blue, the latter very lively in color.

**PROFITS OF ELECTRIC LIGHTING.**—With a view of setting at rest the question as to whether electric lighting has thus far proven profitable as an investment, the editor of the *Scientific American* recently addressed a circular letter to the managers of a large number of electric lighting companies asking for their experience in the matter as a subject of scientific, as well as economic interest. The inquiry was addressed more especially to those employing the Thompson-Houston system. The answers received are generally to the end that electric lighting is paying a better dividend than a majority of new enterprises. The highest returns were from Omaha, where a company, operating four 30 light dynamos, had earned at the end of the first three months after incorporation 4½ per cent on the investment, or at the rate of 18 per cent per annum. Replies were also received from Washington, St. Louis, Worcester, Terre Haute, Auburn, Me., Salem, Mass., Quincy, Ill., Kansas City, etc., which confirm these results, and state emphatically the belief of the writers in the desirability of electric lighting as an investment. These conclusions, although derived from the working of the particular lighting system named, may be equally valid and reliable for other systems now before the public. There is room for great extensions of these local lighting companies in all parts of this and foreign countries.

**HOT WATER FROM ARTESIAN WELLS.**—Parties, partially under the patronage of the city authorities, are boring for hot artesian water at Pesh, in Europe. The expectation is to secure a city supply of hot water. The well, at last reports, was down 3000 feet, with a supply of 175,000 gallons a day, at a temperature of 161°, rising to a height of 35 feet above the surface, and the work is to be continued until the temperature, which progresses regularly as the borings descend, rises to 178°, and then no doubt is felt that there will be a bubbling perennial stream sufficient to meet all the wants of the city and to convert the surrounding region into a tropical garden. According to the degree of success already met with, the project seems quite certain to fulfill the expectation of the projectors. Both hot and cold water flowing from an artesian well through pipes into a house would not only be a novelty, but would be regarded in the nature of a blessing. It is reasonable to suppose that hot water can be obtained almost anywhere if wells are bored deep enough, and if the already partially successful Pesh experiment should demonstrate the feasibility of such schemes, it is easy to foresee that wells would be generally sunk to supply such a universally required thing as hot water.

**INFLUENCE OF TEMPERATURE ON THE STRENGTH OF IRON AND STEEL.**—B. Papkoff gives in the *Russian Mining Journal* an account of an extensive series of experiments on the influence of cold on the strength of iron and steel in various forms and under various kinds of strains, but circumstances obliged him to abandon his intentions after a very few tests had been made. He thinks, however, that the results he was able to obtain are worth being made known, because they seem to point to conclusions totally opposed to those generally received. All the specimens tested were taken from soft steel and iron plates, three samples being cut from each plate. One sample of each group was tested at the ordinary and two at the low temperature. It was found that both the ultimate strength and percentage of elongation increased very sensibly with the decrease of temperature; the author remarks that such a result was to be expected, because the contraction caused by cooling has the effect of bringing the particles of matter closer together, and consequently of intensifying the force of cohesion; but he also observes that a law which may be found general for strains gradually imposed may not apply at all when they assume the nature of shock or of impact.

**THE WASTE OF LIFE.**—An English naturalist remarks it is a sad reflection that while the turbot lays 14,000,000 eggs, not more than one, on the average, ever lives to reach maturity. In fish generally it takes yearly at least a hundred thousand eggs for each individual to keep up the average of the species. In frogs and amphibians a few hundred are amply sufficient. Reptiles often lay only a much smaller number. In birds which hatch their own eggs and feed their young, from two to ten eggs per annum are quite sufficient to replenish the earth. Among mammals, three or four at a birth is a rare number, and many of the larger sorts produce one calf or foal at a time only. In the human race at large, a total of five or six children for each married couple during a whole lifetime makes up sufficiently for infant mortality and all other sources of loss, though among savages a far higher rate is usually necessary. In England an average of four and a half children per family suffices to keep the population stationary.

## Washington Territory Mines.

The Stephens Reporter says: The Colville mining country presents greater inducements to capitalists who wish to operate in argentiferous lead ores than any mining camp at present known to the writer. Why? Because the present owners are nearly all prospectors, and if they felt inclined to develop their mines and reduce these ores to bullion they are entirely unable to do so, and it is doubtful if more than one-half of the prospectors will be able to do the required \$100 worth of assessment work on each location, and the properties must go to the second or third parties before realization commences.

The geography of the country is such that the ores from a large number of mines can be concentrated at a given point for reduction, thus rendering it unnecessary for the operator to use the vast amount of dead flux as is generally the case where only one or two classes of ore are available, as the "charge" can be made up of the different classes of ore with the exception of a little iron, which can be had for the mining and hauling. A good quality of charcoal timber, varying in size from six inches to three feet in diameter, is inexhaustible, and should be delivered for not to exceed ten cents per bushel in quantities, as the producer will neither be obliged to chop or grade roads nor go to the canyons as is usual in other mining localities. The whole country, while covered with good timber, is free from underbrush and open enough to drive a wagon through without risk or trouble.

The ores are usually high in lead, and, with some exceptions, worthlessly low in silver, and yet the field presents surer and more reliable profits for capital than many of the camps where the ores are of a higher grade in silver.

It is a well-established fact that the character of the mines found here are permanent and go down to the deep, while the free, rich chloride mines are always doubtful, and while lead holds above 45 cents we can stand a further decline of 10 cents per ounce of silver, and still make a good profit in the reduction of these ores.

One of the best places for a plant for the reduction of these ores is at or near the Little Dalles, about 30 miles north from this place on the Columbia river. The company could have their own boat, and could ship their bullion up the Columbia river to Farewell, on the Canadian Pacific Railway, thence to Portland, San Francisco or Omaha, or any point in the East. The cost of freight to San Francisco via the Columbia river and the Canadian Pacific would not exceed \$12 per ton. The boat could be run for at least seven months of the year, but the reduction works could go on forever. With absolutely no wind in winter time, and about 14 inches of snow, mining, smelting and milling could be carried on as well as in summer. We are not at the mercy of one single giant carrier that would extract the last penny for freight, only leaving us enough of the profits to go on and extract another cargo.

We claim to be good country-loving loyal Americans, and if our Dominion cousins will handle and deliver our freight cheaper than the Northern Pacific Railway, we shall feel in duty bound to patronize them, as we happen to be in a position to talk back this time.

After the N. P. has extended its Spokane branch to this point there will be room for about a dozen plants in the immediate vicinity of Colville.

**PROSPECTING SOUTHWARD.**—Since the opening of the season the attention of prospectors has been attracted to the very interesting mineral section traversed by the Carson & Colorado Railroad. It is a comparatively undeveloped region, rich in mineral veins and deposits of all kinds not explored enough to give any adequate or definite idea as to its real merits. During the past few months very valuable mines have been brought prominently into public notice through real merit or demonstrated by actual bullion productiveness, as for instance the famous Lapanta, the rich Hindley mine, the Farrington mines, etc.; and now an other strike of very rich ore is reported in North Canyon, about eight miles from Hawthorn. There are many other good mines and prospects being opened and developed besides those mentioned, all of which will be munificently heard from in due time. It is a good county to prospect for gold mines at the present time, when a purely silver mine, even though rich in that popular metal, is considered comparatively poor property, owing to the cost of working and the fearful discount on the bullion product. On either side of the road the mountain ranges are seamed with mineral veins, awaiting the inspecting pick of the enterprising prospector, and the requisite supplies of all kinds are now advantageously accessible at the various towns along the route, or speedily procured by railroad. Prospectors are working in the hills for miles back from the line of the railroad, and many are quietly finding the competence they have so long vainly sought for elsewhere. It is a mining region which is really only in its infancy, and which has a future before it little appreciated at the present time. The Lapantas and the Hindleys are not all discovered yet.—*Virginia Enterprise*.

CAYENNE PEPPER blown into the cracks where ants congregate will drive them away. The same remedy is also good for mice.

## USEFUL INFORMATION.

## Foaming and Priming.

The tendency of the water in a steam boiler to rise into the cylinder is generally attributed to the presence of dirt, grease and other similar substances; but, according to a correspondent of the Cincinnati *Artisan*, the tendency frequently arises from a disturbance of the relation existing between the temperature and elasticity of the steam in the boiler, as when the discharge of steam is out of proportion to the steam room in the boiler the high temperature required to generate steam with sufficient rapidity to supply the demand causes violent ebullition, and the agitation is greater when the relation between temperature and pressure is disturbed. This is often the case with tug boats when just starting a heavy load, or a locomotive starting a train of cars, and even with stationary boilers having too small steam capacity when a heavy load is put on.

The most common causes of foaming are insufficient steam room, foulness of boiler, excessive firing, and the effects produced by the intermittent action of steam valves. The supply of steam to the cylinder being cut off for a considerable period during each stroke, the effect is to throw the water in the boiler into a slight undulatory motion, as may frequently be observed in glass water-gauges. Foaming in locomotive boilers is generally caused by impurities in the water, usually confined to sections of country known as alkali regions, these impurities consisting essentially of potash, soda, ammonia and lithia. When surface water is used, locomotive boilers are apt to foam, if allowed to get dirty, on account of decayed vegetable matter held in suspension in the water, such sedimentary accumulations adding to the strength of the ingredients above referred to.

Foaming is sometimes confounded with priming, but they arise from very different causes and are productive of very different results. Foaming may cause permanent injury to the boiler, or even induce explosion, while priming can only cause waste of fuel and loss of power. Foaming is always made manifest by the violent agitation and rising and falling of water in the gauge; also by the muddy appearance of the water and the particles of sediment brought up from the lower part of the boiler.

Priming may, and does, go on unseen, but can be discovered by the white appearance of the exhaust steam, which descends in the form of mist, while "dry steam" has a bluish color and floats away in the atmosphere. Priming also makes itself known by a "clicking" in the cylinder, caused by the piston striking and forcing the water against the cylinder heads. This is also the cause of one kind of "pounding" or "knocking," and if the water is not let out it is liable to break the cylinder head.

In cases of foaming, close the throttle and keep closed long enough to show true level of water. If that level is sufficiently high, feeding and blowing will usually suffice to correct the evil. In cases of violent foaming, caused by dirty water, or change from salt to fresh, or vice versa, in addition to the action before stated, check draft and cover fires with fresh coal.

**LIFE'S DECAY.**—Charles Kingsley once said: "One of the kind wishes expressed for me is long life. Let anything be asked for me except that. Let us live hard, work hard, go a good pace, and get to our journey's end as soon as possible. Then let the post-horse get his shoulder out of the collar. I have lived long enough to feel, like the old post-horse, very thankful that his end draws near. Long life is the last thing I desire. It may be that as one grows older one acquires more and more the consciousness of the difference between what ought to be done and what can be done, and sits down more quietly when one gets the wrong side of 50, to let others start up and do for us things we cannot do for ourselves. But it is the highest pleasure a man can have who has (to his own exceeding comfort) turned down the hill at last, to believe that younger spirits will rise up after him and catch the lamp of truth, as in the old, lamp-bearing race of Greece, out of his hand before it expires, and carry it on to the goal with swifter and more even steps."

**PIANOS IN WINTER.**—Winter is the heavy season for piano tuners. The heat of a fire soon puts a piano out of tune. This is not due to the expanding and contracting of the strings, as generally supposed, but to the variations produced in the sounding-boards under the influence of the increased dryness of the air, especially in furnace-heated houses. Sounding-boards are made of spruce because of the superior resonance of that timber, but spruce, of all woods, is most affected by changes in moisture.

**ALL PAPER.**—At the late Melbourne exhibition there was a unique exhibition, consisting of a complete dwelling-house, made of papier mache, as was all its furniture—chairs, sofas, tables, beds, bedding, carpets, etc. There was also a paper stove, with paper frying-pans, kettles, etc., in which a bright fire was constantly kept burning. During the exhibition the builder and exhibitor gave a banquet at which all the table furniture—plates, cups, saucers, knives, forks, spoons, goblets, etc.—were likewise made of paper.

**HOW TO KEEP MOTHS OUT OF CARRIAGES.**—As this is a subject of very great importance, especially at this season of the year, we will not wait until we have tested the remedy suggested by an old trimmer, who has been using it for a number of years back, and claims for it a comparative victory over those destructive pests known as moths. His plan is an invisible one, and strikes at the very harboring places they infest. The plan is a mixture of the paste, and will not in any way impair the quality of the paste nor stain the linings, as might at first be supposed. The paste is made up in the usual way with fine tar mixed in it, in the proportion of two tablespoonfuls to a gallon of paste. By putting this in the paste you will readily see that the preventive is distributed throughout the whole carriage. The odor, it is said, remains a long time, but is not sufficiently strong to render it disagreeable to smell; hence the advisability of using it in the carriage business.—*Carriage Monthly*.

**THE FIRST WATCH.**—The first description of a watch extant is found in the "Cosmographia Pomponii Melæ," under the heading "Nuremberg." After a description of the place comes a sentence in Latin which, freely translated, reads: Peter Hele, quite a young man, is making articles here which excite the admiration of even the most learned scientists; out of a small quantity of iron he makes a clock with numerous wheels which will register and strike 40 hours in whatever position it may be laid, and even when carried in the bosom or in the purse. This Hele was born about 1480, and is claimed as the inventor of the pocket-clock, as it is called in Germany. No specimen known to be his work beyond a doubt has come down to us, but some of the Nuremberg eggs were probably contemporaneous with the works of his later years.

**NATURAL GAS AS FUEL FOR LOCOMOTIVES.**—The Pittsburgh *Commercial Gazette* says: "The Philadelphia Co. is arranging to pipe gas into the yards of the Pennsylvania railroad, into a big reservoir that is to be put up there for the purpose of supplying the tanks of engines that are to be run by natural gas. 'The scheme is perfectly practicable,' said an officer of the Philadelphia Co. 'It has been said the gas is so volatile that no tank can be constructed that will hold it. This is all nonsense. We shall demonstrate not only the practicability of confining gas, but the fact that it may be used as a fuel aboard engines so cheaply that, in a short time, not a locomotive running into or out of this city will use coal.'"

**ANY CIRCULAR SAW** should balance perfectly in any position, before and after toothing. By the use of inserted teeth, circular saws may be enlarged from one to two inches effective diameter. Care must be taken with inserted-tooth circulars to have the guides clear the teeth. If the mandrel is a tight fit when cold; it will be apt to spring the saw when it is heated. In order to prevent wearing out the guides of a circular, it will be well to hold the end of a new oil-stone against the disk where the guards touch it; this will polish and furnish a track.

**AN ANCIENT STONE PLOW**, weighing about 300 pounds, has been unearthed in New Jersey, at the old Smith-Clark quarry. The Milford *Leader* says: "It had the appearance of having been cut into the shape of a plow by an ancient people. It was complete in nearly all its parts, and bore a strong resemblance to that sort of agricultural implement used by the Assyrians and Egyptians centuries ago."

**GASOLINE AS FORGE FUEL.**—It is said that the most satisfactory results have been obtained at the Government arms factory in Springfield, Mass., from the use of the vapor of gasoline as a forge fuel. The expense is said to be not even half that of coal, and there are other minor advantages. This success has greatly interested New England metal-workers, who are already beginning to adopt it in several factories.

**PRINTED MATTER MAY BE COPIED** on any paper of an absorbent nature by dampening the surface with a weak solution of acetate of iron and pressing in an ordinary copying press. Old writing may also be copied on unsized paper if wet with a weak solution of sulphate of iron, mixed with a small quantity of solution of sugar syrup.

**IVY AND DAMPNESS.**—An English experimenter finds that, contrary to general opinion, a growth of ivy over a house renders the interior entirely free from moisture. The ivy extracts every possible particle of moisture from wood, brick or stone, for its own sustenance by means of the tiny roots which work their way into even the hardest stone.

**A GOOD PAINT FOR SHEET IRON** is made as follows: Good varnish, one-half gallon; boiled linseed oil, one-half gallon; add red lead sufficient to bring to the consistency of common paint. Apply with a brush. Applicable to any kind of iron work exposed to the weather.

**FROZEN MILK IN FEVER.**—Dr. E. J. Janeway, a New York physician of some note, acting on a suggestion from a colleague practicing in the country, has given frozen milk to patients whose stomachs did not tolerate ice-cream, and speaks highly of its use in fevers.

## GOOD HEALTH.

## Pasteur's Method of Vaccination.

If a section of the spinal cord of a rabid dog be inserted into the brain of a rabbit by trephining, the latter animal becomes mad in about 15 days; and when the virus from this rabbit is transmitted to a second, and from the second to a third, and so on, by the same method of inoculation, the rabies soon become more and more pronounced, and the developing or incubation period becomes shorter and shorter, until, at the end of 50 inoculations, a most severe form of madness results in about seven days. The virus from the last rabbits is of great purity and of invariable strength, so that similar sections of spinal cord may, therefore, be relied upon to produce exactly similar effects. It has been further shown that the virulence of the pieces of cord slowly and quite regularly disappears when kept in dry air and remains unaltered when preserved in carbonic acid gas. An understanding of these principles makes it possible to have constantly on hand hydrophobic poison varying in strength from harmless mildness to deadliest virulence. It is upon these graduated poisons that Pasteur depends for his remarkable method of protecting the animal system from hydrophobia. Experimenting first with dogs, a little meat broth containing weak virus was injected under the skin the first day, and was followed daily by injections of increasing virulence—that is, preparations from cord of shorter exposure to air—until in a few days the fresh or strongest virus was used, when it was demonstrated that, without injury to the animals, had become entirely refractory to rabies from bites—even when inflicted before treatment—or inoculations of any degree. The method was first tried on a human subject in July, 1885, when immunity was conferred within ten days on a boy considered to be in great danger. Since then several hundred bitten persons have been treated, and thus far the only failure to prevent hydrophobia has been in a single case where the inoculations were attempted too late.

## Sunstrokes.

One of the peculiarities of the late warm spell is the occurrence of sunstrokes in the hot valleys of the interior portion of the State. Some of our contemporaries have connected them with the thunderstorms which have recently occurred not only in the bay counties but in the Colorado desert region. One of our city contemporaries says: We have already called attention to the fact that our last storm had its counterpart 10 years ago, and that season was remarkable for its sunstrokes, seven cases occurring near the town of Turlock in one day. Much higher temperatures are felt almost every year than characterized the late heated spell, and no such results have followed. It is embarrassing, however, to be obliged to explain to our Grand Army visitors how exceptional thunderstorms and sunstrokes are in this State, for there are some who will be ungenerous enough to be incredulous.

The following cases of sunstroke were reported within a day or two after the late electric display: At Oroville the deaths include Mrs. T. J. Coffin, a nurse, and Mrs. John Pollock.

Four cases of sunstroke are reported from Moore's Station, Butte county.

In Tehama county there were two deaths from sunstroke on Friday and Saturday. Both were harvest laborers, one being named Leslie and the other Domingo.

Two more deaths are reported near Stockton—James Dooley, a laborer from San Francisco, and Christ. Wall, who was a deckhand on a schooner.

At Sacramento, Saturday, Patrick O'Brien died suddenly from the effects of the heat.

**THE PHILOSOPHY OF VACCINATION.**—Professor Tyndall explains the philosophy of vaccination as follows: "When a tree or a bundle of wheat or barley straw is burned, a certain amount of mineral matter remains in the ashes—extremely small in comparison with the bulk of the tree or of the straw, but absolutely essential to its growth. In a soil lacking, or exhausted of, these necessary constituents, the tree cannot live, the crop cannot grow. Now, contagia are living things, which demand certain elements of life, just as inexorably as trees or wheat or barley; and it is not difficult to see that a crop of a given parasite may so far use up a constituent existing in small quantities in the body, but essential in the growth of the parasite, as to render the body unfit for the production of a second crop. The soil is exhausted, and until the lost constituent is restored, the body is protected from any further attack from the same disorder. Such an explanation of non-recurrent diseases naturally presents itself to a thorough believer in the germ theory; and such was the solution which, in reply to a question, I ventured to offer nearly 15 years ago to an eminent physician. To exhaust a soil, however, a parasite less vigorous and destructive than the really virulent one may suffice; and if, after having by means of a feeble organism, exhausted the soil without fatal result, the most virulent parasite be introduced into the system, it will prove powerless. This, in the language of the germ theory, is the whole secret of vaccination."

## MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

## CALIFORNIA.

## Amador.

**CLEANUP.**—Amador Ledger, July 24: The total cleanup of the Volcano Gold Gravel Mining Company's claim at Volcano for the season's run, amounted to \$19,117, considered a very satisfactory yield. Within the last five days the sale of the St. Julian mine of 1400, feet located at Middle Bar, between the Little Sargent and the Nevill mine, was negotiated by Col. Robertson to Mr. Wm. M. Curtis for the controlling interest, 62,500 shares, owned by A. Caminetti, at about 10 cents per share; 10 per cent down in 45 days; ten per cent in six months, balance, one year. The same rate paid for the control will be paid for the rest of the stock should the parties desire to sell. Col. Robinson is sinking on his Middle Bar mine at Middle Bar, and will likely consummate a sale soon to San Francisco capitalists for one-half interest for mill and hoisting works. The ore assays \$20 per ton. The Amador Queen mine and mill have been idle for several weeks. Half a dozen laborers' liens, to secure wages aggregating \$500, were filed against the property last Wednesday.

**SUTTER CREEK.**—The Mahoney Co. have decided to commence operations again on the surface. They have two or three men at work laying a track to the mill, and in a few days they will have a number engaged in running surface dirt to the mill. There is any quantity of rock, and every reason to believe that it will pay the company handsomely for crushing. Operations at the Amador Consolidated are still at a standstill. It is known that it is the intention of the company to keep the water out, but beyond this everything is involved in uncertainty. The break that occurred in the pipe that carries water to the Lincoln has been repaired, and everything is running in regular order once more. The 10-stamp mill of the Iowa will be completed this week, and in all probability the stamps will start next Monday.

**SHUT DOWN.**—Amador Dispatch, July 24: The mill at the Live Oak mine has been shut down for awhile, as the owners are engaged in sinking the shaft and prospecting lower down.

## Calaveras.

**ANGELS MINING NOTES.**—Mt. Echo, July 21: The Tozer mine, though lying idle at present, will start up anew shortly. Steam is generated tri-weekly for the purpose of freeing the mine of water until all the necessary preparations are made for resuming work again. The Lane mine is running in full blast. The batteries are kept in constant motion, and it is reported that very good rock is being extracted. Everything has the appearance of life and activity at the Stickle mine at present. Work is being executed vigorously day and night in the mine and at the mill. High-grade ore is being mined, and an unparalleled yield is anticipated at the next cleanup. The Jones mine, situated at the mouth of Carson creek, has recently been pumped out. As soon as the requisite repairs are made operations will be resumed. The Gold Cliff mine is running night and day and a vim never heretofore exercised for proving the true value of this immense ore deposit is being indulged in in a manner born of true energy. The stamps send forth their thundering roll over hills and plains, mingling their sound with the numerous other mills in this vicinity, sending gladness to the hearts of our miners and residents in general.

**MINING ACTIVITY.**—Calaveras Chronicle, July 24: There has been considerable activity noticeable of late in the mining interest. And while we feel some shyness in placing too much confidence in the little boom which we are having, from the fact of having experienced a number of such awakenings in this interest which resulted in making us sadder and a little wiser, still, for all our several disappointments, we have again occasion to renew our hope and expect good developments in the quartz interest in this part of the county. It can hardly be called a boom, for the stir is not sufficient to warrant the designation, and we are not sorry for that, either, because we have had all our faith in a "boom," according to the common acceptance of that term, knocked clear out of us. But the late moderate activity partakes more of the air of business, with the noticeable absence of any "splurge," or desire to make great bluster and blow, which, in mining operations, looks very suspicious, and which experience has taught will be followed by no good results. Those persons who are looking for chances for profitable mining investments in this vicinity at present are plainly of the kind who do not court publicity as does the adventurer, who, without means, depends upon an outward show and boom to afford a temporary good living, by the wholesale swindling of too credulous creditors and unsuspecting laborers. Whether or not the renewed activity will prove of permanence and turn out profitable will remain to be shown. We can say, however, that the evidences warrant the belief that there will be a marked revival of the quartz-mining interest in this vicinity, and there will be good mines opened. In the Middle Bar district things are looking very flattering, the best prospects, however, being confined to the Amador side; but it is a very sure thing that valuable quartz discoveries will be made on the Calaveras side. A great deal of prospecting is going on in that neighborhood, and the results are encouraging for the prosecution of work on several locations there. The Quaker City mine, located at the Junction, about three miles south of this place, is a piece of property which has lain idle for a number of years. About a year ago a tunnel was started to reach the lead which had been worked to a certain depth by means of a shaft. Work in pushing the tunnel was prosecuted only at intervals and not continuously during that time, but now the mine has been bonded to San Francisco parties and work in the tunnel has been resumed. Seventy-six feet more of tunneling will tap the lead at a depth of 250 feet. At Rich gulch a mill is being constructed on the Eureka mine, which will soon be completed and running. In the Blue Mountain district the famous Fine Gold mine continues in operation, and though

no report relative to the mine has lately reached us, we believe everything is working with satisfactory results. We are expecting to be able to chronicle some successful operations in that neighborhood at an early day. We have received no report from mines in West Point district for some time past, but we believe that the enterprises in that locality are being steadily pushed ahead. The Tiger mine, at Rich gulch, has recently been sold for \$20,000 to an Eastern company. A new 10-stamp mill has been erected at Railroad Flat on the mine of Messrs. Carigan & Jones. In a word, the signs are encouraging in the prosecution of quartz mining.

## El Dorado.

**MT. PLEASANT.**—Placerville Republican, July 23: The old Mt. Pleasant mine continues to send up first-class ore from the 700-foot level, and the entire people of the neighborhood are jubilant. One hundred tons of fine-looking ore from the Eagle King mine near Grizzly Flat is being crushed at the Mt. Hope mill and promises a good return.

## Inyo.

**BOTH GOLD AND SILVER.**—Independent, July 24: For some time past Reynolds and Treglown have been working a mine at Eclipse, about seven miles south of Independence Station. They worked only for galena ore, but under this, and separated from it by a few inches of clay, is a vein of quartz. Some few weeks ago a few tons of the quartz was saved and milled, and yielded \$24 a ton. Now all of the ore is saved, and will be shipped to the Maxim mill to be worked. During the past ten days the mill has been overhauled and put in thorough repair, and a side track is being put in from the C. & C. railroad. The quartz vein in the mine is two feet wide, and being mined with the galena ore the cost of getting it out is but little. The condition of the veins in this mine appears to be very much like that of the neighboring Brown Monster.

## Lake.

**MORE ORE.**—Lakeport Democrat, July 24: The Great Western mine has recently been reported as worked out and shut down. On the contrary, it has just struck a rich deposit of ore, and is driving ahead with better prospects than for many years. The Bradford brothers have a very excellent mine, and are working it in a small way and all making money. There is reason for believing that it will prove to be the richest quicksilver mine in the county.

## Mariposa.

**BUENA VISTA.**—Cor. Mariposa Gazette, July 24: Last week I went around the several mines to get a few items. The Buena Vista mine is getting in good order and ready for a start. Everything about the mine and mill is getting ready for crushing the quartz rock. The mine looks like an everlasting good mine; it is 10 to 12 feet in width, and very extensive, and has a 10-stamp steam power mill already to start.

**THE PADDY MCCANN MINE** on Sherlock's, run by Dr. Robinson, who is chief engineer and manager, is getting ready to start up a five-stamp mill on the same. This mine is a talc formation, carrying coarse and fine gold; it is very soft and easily crushed. Everything about the mine is in good shape.

**THE DILTZ MINE.**—Captain Diltz is still hard at work on his mine, and is showing up a splendid vein. There is sufficient rock already out to run a 10-stamp mill a good many years with a big profit. A good mill is what is most needed.

**SCHANZ MINE.**—Joe Schanz is at work on a vein just below the Diltz mine on Sherlock's creek with a fine prospect. The rock is rich in fine gold. Nothing like grit, and Joe is full of it. Ellingham, Grove & Co. have a mine on Whitlock's creek, and a prospecting mill of two stamps. Their vein is good size and prospects well, and it is thought they have a valuable mine.

**RUMLEY MINE.**—Rumley has gone to the mountains and left David Egenhoff and F. Davis in charge. They are sinking a shaft on the mine in hopes of finding the other end of a rich pocket.

## Mono.

**BENTON ITEMS.**—Bodie Miner, July 21: Miller's mill is running along steadily. The chlorides on the hill and up in Montgomery canyon are doing fairly well. Tucker & Mitchell shipped two tons of silver-lead ore on Tuesday. M. Harrington is taking out some good ore again. P. Dowd, Joe McDermott and several other persistent prospectors have been making a few developments on some of the gold ledges of Clover Patch and in the vicinity of the Wild Rose.

## Nevada.

**BADGER.**—Grass Valley Union, July 20: Since the Badger mine has been pumped out, a good-sized vein shows in the incline and drift, but it is found that much waste material left from former workings will have to be cleared out before systematic development can be commenced. The vein carries good-looking sulphurets.

**NEW MILL.**—North San Juan Times, July 24: We learn that a quartz mill for the new quartz mine on Armstrong's ranch below Sweetland has been ordered from Downieville. It will cost \$500 and crush from 15 to 20 tons of rock in a day. It is said that the company have 1000 tons of rock mined ready for crushing, which will pay from \$6 to \$10 per ton, if not more.

**BEATS THE DAYS OF '49.**—Nevada Transcript, July 21: John Curry, who, on the 10th of this month, struck a pocket of rich ore while sinking on the old Joe Lopez ledge out on Rush creek, brought to town recently a gold bar worth about \$850, it being the result of two days' work in the claim. In pioneer times an ounce a day was considered pretty good pay for mining. Curry thinks there is plenty more gold left where he got that from which he brought in yesterday. It is the same ledge in which Joe Lopez a few years ago struck a pocket that produced \$18,000 or \$20,000 in a few days.

**GENERAL NOTES.**—Foothill Tidings, July 26: The Idaho has just paid its 20th dividend, and on the first Monday in August the grand old mine will pay another dividend, and if no unforeseen accident happens it will keep on paying for years to come. The Badger mine is now entirely pumped out, the main shaft being to the depth of 175 feet on an in-

cline, while the shaft sunk about midway on the main shaft is down about 190 feet from the surface. The water is now easily controlled, and a contract has been let to sink No. 2 shaft 25 feet deeper. Z. Mansau is preparing to erect machinery on the Coe mine, and as soon as it is in place, work will be commenced. Work is steadily going ahead at the Horseshoe. The ledge in the drift is 2½ feet thick, and of good healthy quartz. There is every prospect for a good mine there, and the company is in exuberant spirits over the discovery of such good-looking quartz in such a ledge. This is supposed to be an extension of the famous Allison Ranch. Back of Watt Park, R. Connolly and R. Ryan, with their partners, have erected a pumping engine and a whim for hoisting, and now have a shaft down 100 feet on a well-defined ledge, the ore from which yields from \$13 to \$15 per ton. We could not learn the name of this prospect. The miners have only been working upon it a short time. The Gold Point mine has a 2½-foot ledge. There are now 1200 feet of drifts in the mine, 500 feet being on the course of the ledge. The company will soon introduce water power into the mine, having already made a contract with the Grass Valley Water Company to furnish water for them. There are now about 100 loads of ore from the Gold Point waiting to be crushed. The Central mine, on Greenhorn creek, is looking well, and the company is pushing work ahead as fast as possible. A Hill roller-mill will be in operation on the property by the first of next week. Orlando Stoddard has charge of erecting the machinery, and Wm. Fowler has been appointed superintendent. Three Triumph concentrators are already in place ready for their work. The ledge in the Central (old Greenhorn) runs all the way from 3 to 6 feet in thickness, and is good bearing. The North Star mine is looking better all the time. A quartz mill, like that built by W. C. D. Body at the Empire, will soon be erected on the North Star. Bids for sinking the shaft on the St. John (Knights of Malta) will be received through the postoffice. The mine will soon be put into condition for thorough development. The Crown Point mine is still turning out pay ore, and soon a larger and greatly-improved mill will be erected. There is good ore coming out of the Pennsylvania. The lessees feel greatly encouraged with their prospect. The Lone Tree Company is busy making arrangements for the erection of machinery on the mine. It will take but a few weeks to complete this work. The Leami Company (gravel) is now preparing to resume work. The owners in this claim feel confident that they are on the old Alta channel.

## Placer.

**NEW DITCH.**—Placer Republican, July 21: Mr. Burleson, superintendent of the Lee mine near Rocklin, has been making a survey for a new ditch, by which it is proposed to take water out of the American river above Lyons' bridge. It is designed to supply water to the Rocklin mines and to the ranchers along the route. The proposed capacity is 3000 inches.

## Plumas.

**NORTH FORK.**—Plumas National, July 23: There is a good deal doing in our North Fork mines, and a good deal of prospecting is going on in various localities. Jeff. Buffington lately made a good strike at Cariboo. Baptiste Piazoni has reached gravel in his drift diggings. All work has been stopped at Dutch Hill in consequence of the hydraulic injunction. Work has recommenced at Sunnyside. About all the Big Flat country has been located in gravel claims.

## San Diego.

**MINING PROGRESS IN THE SOUTH.**—Los Angeles Herald, July 24: There is a steady improvement in mining matters wherever the heat of the weather does not interfere with business. There is no great bonanza discovery, but a steady increase of small mills and mines. The Julian mines of San Diego county seem to be steadily improving. The Stonewall continues pouring out a steady golden stream. The Owens mill has just crushed 60 tons of ore that yielded the remarkable sum of \$15,600, or \$260 per ton. The Shenandoah has made a rich strike, and now the strife will be between the Owens, Shenandoah and Stonewall mines to see which shall be the greatest. There are many other mines that are being opened with gratifying prospects in the neighborhood of the Shenandoah. The mines on the desert near Yuma are wonderfully rich, but are not pushed now on account of the heat of the weather. Pinacate is also a steady bullion producer of gold. There are many other districts in that county where gold is abundant and only needs a railway near and some capital to bring it out, so that San Diego may be called a permanent and large-producing county.

**JULIAN.**—San Diego Union, July 22: Bailey brothers, of the Ready Relief mine, have a fine body of rich ore opened, and are doing well. The Owens mine, situated on the hill just above the town, is in good shape and is a very valuable property. The main or working shaft is down 200 feet, and still sinking deeper. The levels running from the shaft develop a body of pay ore from three to four feet wide, and as far as developed 200 feet in length. The mine is provided with a fine new 10-stamp mill, which is kept running day and night, when they have a sufficient quantity of water. This defect will soon be overcome, and then look out for a large yield of bullion. They have about 300 tons of ore on the dump, which good judges say will not average less than \$25 per ton. The Stonewall mine, situated in the Cuyamaca valley, is doing a fine business. They have a pay chute of ore from 4 to 20 feet in width and 200 feet in length. Many good judges say that this is the best gold-bearing mine in the State. They also run a 10-stamp mill day and night. One thing sure—we may all look for a good record from the Julian mines for the next two years.

## Shasta.

**MILL.**—Shasta Democrat, July 21: We are informed that Mr. Day has bought his partner's, Hart's, interest in the Georgia & Texas mining property in old Diggins district, and is preparing to rebuild a 10-stamp mill. Last week an eight-foot vein was struck in the Snyder mine, Squaw creek, and the best of it is the ore prospects and shows lots of free gold. The strike is a big thing for the camp. Mr. Myers, who owns a promising mine in French Gulch district, adjoining Scorpion, last week shipped a boiler and engine here, purchased in Grass Valley,

with which he will run his cannon-ball mill. He expects to be crushing by the last of this month. The coal discovery east of Millville promises to be a bonanza. There are three distinct veins which have been traced for over a mile. A force of men is at work putting up the machinery on the Salt Creek tellurium mine. Mr. Scheerer thinks the works will start up in two weeks.

**IRON MOUNTAIN.**—Courier, July 24: There are various rumors as to what will be done at the Lost Confidence mine at Iron Mountain. There is a hitch between parties interested in the mine and machinery, and until these differences are terminated nothing definite will be known. We are informed that unless a satisfactory arrangement can be made the immense plant of machinery will be removed from the mountain, and in that case the district would be put back for half a generation. Sam Blue, who owns a very good mine on Iron Mountain, came down to town this week, the lonesomeness of the mountain being too oppressive for him. Three months or so ago there were about 250 men on the mountain; now the number can probably be represented by counting the fingers of the human hand one time, and the wheels of the great new mill stand unturned and the stamps give forth no sound. We hope to see all differences between parties interested in the mill and mine adjusted, so that the scene may be quickly changed.

**FRENCH GULCH.**—Free Press, July 24: Tom Green's new stamp mill has commenced running and is working well. The mine is very rich and splendid results are anticipated. On Friday, July 16th, the Scorpion Co. blew their whistle for the first time. Col. Gannon is here looking after things. They have a vein of good ore. Mr. Myers, proprietor of the Enterprise mine, has just returned from below with a new boiler, and the mill will be running again in a few days. The Niagara mill keeps pounding away on good ore. The contract tunnel will be in by the last of the month. The Washington Co. is taking out good ore.

**AT SUNNY HILL.**—Anderson Enterprise, July 23: Here we found things much after the old order, unless we except Gray Eagle mine and mining operations. Mr. Loomis, the superintendent of the Sharp Mill and Mining Co., was very polite, and kindly showed us through the mill. From that gentleman we learned that the mine was turning out large quantities of very good milling rock, the rock averaging about \$25 per ton, and the mill working about 15 tons in 24 hours. Everything about the mill and mine is well arranged, and we congratulate the owners of the Gray Eagle mine upon having what we believe to be a rich and permanent mine. We did not visit the Tim Quinn mine, but learned that Messrs. Frank & Driscoll were working the same with favorable prospects ahead.

**THE CALIFORNIA MINE.**—This is the name of a new mining location made on Monday last, and the editor of this paper is the fortunate owner of a half interest in the same. The location is north of the Gray Eagle, and has an immense surface showing. This mine will prove a bonanza because Joe Davis is connected with it. It is not for sale.

## Sierra.

**TOO MUCH WATER.**—Tribune, July 23: The Butcher Ranch mine was closed down Wednesday morning on account of there being more water in the shaft than could be handled. The pump was taken out and the 15 or so employees discharged. Mr. Van Slyke, the owner, intends to run a tunnel into the ledge.

**THE BALD MOUNTAIN** owners have been running a tunnel into some new ground, and it is said they have struck a large body of gravel that looks well. However, they have not got in far enough yet to determine the value of the deposit. It may afford them a couple of years' work yet.

**GRAVEL.**—Mt. Messenger, July 24: Good prospecting gravel was struck, last week, in Deadwood, Northern Sierra. D. Rouse contracted for half the mine, to run the main tunnel to the pay streak.

**GOOD PROSPECTS.**—Tribune, July 23: The Grover Cleveland mine is located about three miles northwest of the Young America, and is owned by Sierra Valley parties. The prospects are that this is going to be a big mine. Very rich rock has been struck, and naturally the owners are jubilant. From 25 cents to \$1 per pan is obtained from decomposed rock that comes from the ledge. An assessment of \$2000 has been levied by the company for the purpose of thoroughly prospecting the claim, and we are told that if the prospects continue as favorable as they are now a mill will be erected in a short time.

**A SEASON CLEANUP.**—A cleanup for the season was made at Hughs' & Osterman's gravel claim a few days ago, and \$6000 obtained. The claim is located near Gold Lake, and is worked on a small scale. P. Lamping was down from the Primrose mine Sunday. He has several men at work there getting things in readiness to put in the pump and clear the shaft of water. A saw-mill is also to be rigged up for the purpose of getting out lumber with which to erect a boarding-house and make other improvements. A San Francisco company has come into possession of the Way & Cobb quartz mine at Cold Spring, six miles southwest of Forest City, and it is said that a 60-stamp mill will be erected on the claim.

## Siskiyou.

**ORO FINO.**—Cor. Yreka Union, July 21: The mines have all shut down. The Eastlick claim, making a run of 166 days and finished cleaning up and retorting on the 13th, carried their gold dust to the Fort on the 14th inst., and report having 1531¾ ounces, which would make a total of \$23,733.25 at \$15.50 per ounce. Wright & Fletcher have cleaned up, but I am not advised as to the result. Many rumors are afloat, placing the amount all the way from \$2000 up to \$10,000. R. H. Campbell, I understand, took out \$7000 and worked mostly top dirt this season. He will put on a lifter this coming season and no doubt will make another \$25,000 cleanup or more next year, as he has some of his best ground to bottom the coming season.

**SCOTT BAR.**—Robinson, Classen & Co.'s quartz lead still continues to pay exceedingly well. They have a good piece of property which, if it continues to pay as it does (which there is no reason why it won't), they will have all they want; the only trouble

is that they have no practical way of working it other than with a mortar. Tompkins' lead continues to pay well. It is a continuation of Robinson & Co.'s. Bennett & Co. are hoisting out the gravel, but as yet they have not cleaned up. Magoffey and Ingram have made quite an opening in their claim, but they have not struck anything wonderful as yet. The Quartz hill miners cannot put in over half time on account of the intense heat and the scarcity of water.

**ETNA.**—Cor. *People's Cause*, July 24: The miners in this section are not so unfortunate, having the Klamath river into which to deposit their tailings, there being no farming country nor navigable waters to interfere with. I had the pleasure of seeing a large shipment made from here to-day of over 300 pounds from Wells, Fargo & Co.'s office at this place, R. H. Campbell acting as special messenger as far as Yreka. There is about \$100,000 shipped annually from the Etna express office, Fort Jones and Callahan's about the same, making \$300,000 annually from Scott valley, besides what goes from Yreka, making perhaps a half million shipped each year. I am told that the mines in this county are only worked on a limited scale. With the railroad now coming into this county, I have no doubt that capitalists will invest in Siskiyou county mines, which will then rank foremost with the best gold-producing counties in the State. Mr. Campbell is also interested in a mine on the south fork of Salmon river that is paying handsomely. It is managed and superintended by G. C. Spooner, an old hydraulic miner of 30 years' experience in Nevada county.

## NEVADA.

## Washoe District.

**CHOLLAR.**—*Enterprise*, July 24: The south lateral drift from the 3200 level, Combination shaft, is now in 55 feet, following along the east clay of the recently developed ore vein in the west face of the station, keeping to the east of it. Formation, dry porphyry with a little quartz. The north lateral drift from the station is out over 100 feet, being now about 40 feet into Norcross ground. It is intended to follow along the east clay wall of the recently developed ore vein in the west face of the station, but the last 20 feet grazed into the vein, showing better ore than was found in the station face. This is a significant circumstance, as showing improvement to the north and east. Connection with this drift and that from the Hale and Norcross deep winze will be made to-morrow, if not sooner. It will take a few days then to straighten up the joint drift and put it in proper working order, after which three crosscuts west will be started, one in the face of the station and two further north.

**SAVAGE.**—On the 600 level no further advancement has been made in the face of the main south lateral drift, which ended in a vein of good ore stated to be 15 feet or more in width. Crosscut No. 1, south of the Gould and Curry line, stopped in the east clay wall, and a crosscut west, opposite it, is now out 75 feet from the main south lateral drift in very favorable ore-vein matter. About 100 feet further south an east crosscut was run 65 feet to the east clay wall, and from it a drift is now being run southeast along the clay wall. The face of this drift is now in good ore, and nearly opposite the ore body developed in the face of the main south lateral drift. These points being 65 feet apart indicates a greater width of the ore body than has been supposed, and the further development thereof during the next few days will be of considerable interest to Savage mine-owners or holders of the stock.

**HALE AND NORCROSS.**—On the 3200 level the lateral drift south from the bottom of the deep winze will make connection with the north lateral drift coming from the Combination shaft this evening or to-morrow. A crosscut east was started yesterday 100 feet south of the winze station to run through to the east wall in order to see what is to be found in that direction. The lateral drift north from the winze station is out 77 feet. All the new drifts on this level in this mine or in the Chollar from the Combination shaft are in dry ground, no water being encountered. Good ore has been found on this level near the south line as mentioned in the Chollar report.

**BEST AND BELCHER.**—Connection was made yesterday with the fourth line of Cornish pumps below the lowest or 2310 level, ready for the further regular reduction of the water preparatory to deeper sinking. The heavy stone bulkhead on that level to shut out the inflow of water from the northward is being commenced. Both these measures will materially reduce expenses hereafter as far as handling the water is concerned. On the 600 level the northwest branch drift from the main west drift has been cleaned out for 200 feet, and this work is being continued in resumption of explorations in that direction.

**POTOSI.**—Chambering out for the header for diamond drill hole No. 6 near the Chollar line is concluded, and the drill will be started east into the vein to-morrow. Drill hole No. 5, farther south, had to be abandoned after reaming out and pushing the drill a few feet further ahead, the hole being too long for easy working, yet the east side of the vein was not reached. It is apparently 200 feet or more in width at that point.

**CON. CALIFORNIA AND VIRGINIA.**—The southwest drift on the 1550 level, and the northwest drift on the 1400 level, are both making good progress, and the repairs to the shaft station on the 1500 level are about concluded. About 350 tons per day is the regular yield of the mine, assaying according to battery samples at the mills about \$11 per ton.

**CROWN POINT AND BELCHER.**—About 300 tons is the regular daily yield, keeping the Mexican, Santiago and Vivian mills steadily supplied. The ore breasts and stopes being worked are from the 1700 up to the 1100 levels.

**OPHIR.**—On the 1300 level the south drift from the shaft is advancing well in favorable vein material. On the 300 level the crosscut west makes good advancement.

**SIERRA NEVADA.**—North lateral drift No. 2, from the west crosscut on the 520 level, has been advanced 50 feet, making a total of 350 feet. Material, vein porphyry with a little decomposed quartz.

**GOULD AND CURRY.**—On the upper level, 150 feet above the track floor of the 600 level, the exploration drifts west and north are progressing well in favorable vein material giving low assays.

**MONTE CRISTO.**—About 40 feet further remains to be run with the drift west on the 150 level from the new shaft in order to crosscut the old ore vein of the mine.

**YELLOW JACKET.**—The old ore stopes and breasts are holding out finely, and shipping to the Brunswick mill the regular daily yield of about 140 tons per day.

**ALTA.**—On the 700 level the west crosscut is expected to cut the old Keystone ledge during the coming week.

## Eureka District.

**ORE SHIPMENTS.**—*Sentinel*, July 24: During the past week ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Eureka Con. Works—Dunderberg mine, 50 tons; Lord Byron, 9½; Scott, 1½; War Eagle, 1½; McElroy, 3½; Last Chance, 2; Mexican, 2½; Morey, 14; Bay State, 12. To the Richmond Works—Silver Lick mine, 46 tons; Marguerita, 2½; Last Chance, 1½; Wide West, 2; White Pine, 7; Jackson, 71.

## Lewis District.

**THE PITTSBURG MINE.**—*Tuscarora Times-Review*, July 21: It will surprise many to learn that the Pittsburg, lying four or five miles from Lewis, and 25 from Battle Mountain, is a magnificent mine. It is now owned by J. A. Blossom, who has negotiated half of it in exchange for a fine 40-stamp mill with machinery to double its capacity. General Foreman is at the mine arranging for the erection of the works. The ore goes \$40 in gold and works over \$24 a ton. It has turned out over \$100,000. The ledge is from 8 to 12 feet wide everywhere. It breaks out on the side of a canyon and four tunnels start in on the ledge and run in on ore all the way. The bottom one is back 500 feet and every one has ore. All the prospecting and developing have been paid for by ore from the mine worked in a little Huntington mill.

## Tuscarora District.

**NORTH BELLE ISLE.**—*Times-Review*, July 24: The crosscut near the shaft on the 150-foot level has been extended 9 feet.

**NAVAJO.**—The south drift on the east vein, 350-foot level, has been extended 16 feet. The south drift on the west vein, 150-foot level, has been advanced 10 feet. The stopes on the 150 still yield the usual amount and grade of ore. Mill running as usual.

## ARIZONA.

**SILVER BELT MINE.**—*Prescott Courier*, July 23: The Silver Belt mine, in Big Bug district, is one of the properties that will soon again be contributing to the wealth of the country. When properly worked it never failed to pay, but, like most mines in new countries, it has had its setbacks, not because of the poverty of its ores, not because the ledge was too small, but mainly on account of high prices, isolation and a lack of harmony among its owners. It is situated about 16 miles east of Prescott, in a section of country that is easy of access. Not long since rains threatened to cause a cave in the shaft, and in digging a drain to conduct the water much rich ore was discovered near the surface, a fact which proves that nothing like the full ledge had ever been seen in sinking the shaft.

**HASSAYAMPA MINES.**—There are no better mines than those which prospectors have partially developed in Hassayampa district, some 12 miles south of Prescott. They carry gold, silver and lead, are of good size and surely permanent. The best of them belong to David Grubb, G. H. LaBerte, W. C. Flint, H. A. Bigelow, Wm. Jennings, Theodore Otto, Geo. Wickler, P. A. Craigue and Jack McDonald. Other miners, whose names we cannot recollect, have properties almost, if not quite, as good. The Senator and Dosoris have yielded hundreds of thousands of dollars. The Catocin, another valuable mine, is near the section we speak of. With reduction works at or near Prescott these mines, with those of Walker, Weaver, Groom, Turkey, Peck, Bradshaw, Cherry and other adjacent districts, will be made to yield carloads of the precious metals, and yet there are people here in Prescott who know very little about these mines or the wealth they contain.

## COLORADO.

**LAKE COUNTY.**—*Herald-Democrat*, July 20: Mr. Hassell and other large stockholders in the St. Kevin Mining Company have formed a corporation for the purpose of erecting a concentrating mill, adapted to the treatment of the low-grade ore product of the St. Kevin. Since the incorporation of the Hassell Milling Company, no time has been lost in carrying out its objects. During the past few days a complete mill was purchased, embracing a 50-horse power boiler and engine, pulverizing machinery and approved concentrating tables. The entire outfit is now on its way to Leadville. The site selected for the new mill is in St. Kevin gulch—a short distance above the place formerly occupied by the Pacific mill, recently destroyed by fire. Grading for the new mill is to be commenced to-morrow, and its completion is to be hastened along as rapidly as possible. The materials for the new mill, to be erected by Mathews & Webb, of Denver, and others in Tennessee Park, near the mouth of St. Kevin's gulch, are already on the ground. The mill, which is said to be a first-class one and exactly adapted to the mineral it is designed to treat, was formerly in operation at Silver Cliff. The owners expect to have the mill erected and machinery in place ready for operation in 30 days. Major A. V. Bohn, who took a lease a short time ago on the Last Chip lode, on the west slope of Fairview Hill, is drifting in a strong body of vein material. The developments up to date disclose a well-defined mineralized seam, but whether it is situated in a fault crevice or the regular lime porphyry contact we do not know. The work in either event is favorable, and likely at any time to disclose good ore. It is only a short distance west of the great mines of Fryer Hill, and the chances for an extension of the ore to this point are quite good. Major Bohn feels sanguine of ultimate success, and will continue until the ground is thoroughly proven up. The principal product of the Only Chance mine, on Rock Hill, is obtained from a winze, sunk below the main workings. This source of ore supply yields about \$3000 a month.

Preparations are in progress for the starting of a deep, new shaft on the southeast slope of Carbonate Hill, near the point where the North Star drill-hole was put down some years ago. Deeper work in the O'Sullivan mine is proving productive. Developments below the acknowledged plane of contact have disclosed ore from which assays have been obtained of 126 ounces in silver to the ton, and 70 per cent in lead. The Iron Mask mine, at Red Cliff, resumed active shipments again last Tuesday, when it sent 15 cars over the Eagle River branch of the Denver & Rio Grande Railway, consigned to Leadville smelters. The managers of the property expect hereafter to maintain a regular shipment of 14 carloads a day.

## IDAHO.

**QUARTZ.**—*Coeur d'Alene Record*, July 20: The *Record* has several times referred to the Margaret mine, which was one of the first, if not the very first, quartz location made in the Coeur d'Alene, and which shows such evidences as seem to warrant the conclusion that it will also rank among the first in value. It will be remembered that the Margaret is on Bald mountain on West Eagle creek. Seven months ago a company was incorporated under the laws of the State of Oregon, with the following named officers: D. C. McKurcher, president; Dr. E. O. Smith, vice-president and general manager; W. L. Newbury, secretary; L. G. Clark, treasurer. The capital stock is \$100,000, divided into 100,000 shares of \$1 each. Twenty-five thousand shares are set aside as working capital, and in addition to this provision five of the stockholders have entered into an agreement, which is duly recorded with all the legal papers, both in Oregon and Idaho, to contribute 25,000 shares more in case it is found necessary in order to get the mine to working upon a paying basis. But careful estimates show that the first provision is likely to be ample. At a depth of 82 feet the vein is eight feet wide and shows chloride, black sulphurets and brittle silver, and assays across the vein run from 50 to 1300 ounces in silver. The stock is made non-assessable.

**FOUR HUNDRED TONS OF ORE SOLD.**—The Montana Co., of Yankee Fork district, have sold to the Custer Co., the contract being closed a week ago yesterday, the entire old dump of the Montana mine, consisting of 400 tons of low-grade or third-class ore, and the ore will be removed at once to the Gen. Custer mill for reduction. The price paid was \$10 per ton on the dump. The Montana Co. have six tons of 200-ounce, or second-class ore, which was mined last year, that they will ship at the same time for reduction. Duncan Cameron went over to the mine Thursday to let the purchasers have the Montana's ore sacks so shipping could be commenced, and returned Saturday.

**OLD LOCATIONS.**—*Idaho World*, July 20: Prospects of late have been taking up and working old locations, well knowing that many quartz veins that would not pay expenses of working 15 or 20 years ago can now be made to give fair returns above all expenses. The old locations, abandoned many years ago, that now give promise of soon being classed as permanent mines, are those now being worked in Lewis gulch; the Cleveland, in Gambrian district, ore from which was recently crushed by the Forest King mill. The location near Grimes' creek, owned by J. W. Pharris and Charley Cooper, and which they are now developing, will no doubt pay. This is the first work that has been done on it for 20 years. The present owners will soon tap the vein in a new place, at the depth of 40 feet.

**RABBIT CREEK.**—Walt Galbreath came in a few days ago from Rabbit creek. He will return to-day. Walt and Conrad Haag own a recently-discovered vein of quartz over there, and are developing it. They are now running a cut and are down about 12 feet. The vein is narrow, but carries rich ore. Walt uncovered the vein the other day 20 or 30 yards from the discovery hole, and there it is even better than where first discovered. The ore carries both gold and silver, the former predominating. Walt brought in a number of specimens that were pretty freely speckled with gold, and liberally sprinkled with silver. He says the vein is no thicker than a knife-blade in places, and at the widest is six inches. It is an encouraging prospect, but the owners are not excited, and say they really have nothing yet to blow about, or on which to build big expectations. With the limited amount of development that has been done, it is entitled to the distinction of being called a very promising prospect.

## MONTANA.

**THE PILGRIM INCORPORATED.**—*Helena Independent*, July 22: Articles of incorporation were filed to-day with the secretary of the territory of the Bozeman Gold and Silver Mining Company with the following well-known incorporators: Hon. Samuel Word of Butte, Walter Cooper, Lester S. Wilson, John S. Mendenhall and Henry Fielding of Bozeman. The property to be worked by this company is known as the Pilgrim mine, owned by Walter Cooper, Esq., of Bozeman, and has been in course of development since August 1st, 1885, and has been a large producer of very rich gold and silver ores, a carload of which has been sampled in Helena, the result being most satisfactory. A number of carloads were also shipped to Omaha last winter. We have never seen any mention of his property in the territorial papers, but from experts and persons who have been on his premises and examined his property we learn that it is a large ore producer, and one of the finest properties in this Territory for the amount of development, which consists of a two-compartment shaft 103 feet deep and about 550 feet of levels and crosscuts. A first-class hoisting and pumping plant has, we learn, been ordered, and will be placed in position at an early day. The mine is located in Madison county, some 20 miles from Bozeman, and is surrounded by rich prospects entered years ago, but many of these old ones have been re-entered, and new locations made in the camp.

**NOTES.**—A contract has been let by the Hot Springs Mining Company to sink a perpendicular shaft 100 feet on the lead in order to prepare the property for effective working. The contract will be completed in about 40 days, and a large amount of ore will be taken out during the progress of the work. Hope Mining Company shipped 7051 ounces

of silver on July 2d, a half-month's run. The stockholders say that if the Hope proves a true fissure, as they have every reason to believe, the mine will rival the Granite. Mr. John Longmaid has been visiting the Cooke mining district, and is said to have been there in the interest of Helena capitalists. Cooke correspondent of the *Bozeman Courier*: The Republic company are doing finely, and turning out some very rich bullion for themselves, and helping the camp by buying ore from several of our mines, thus furnishing funds for the development of mines, which would otherwise only be represented.

**THE HAPPARANDA PLANT.**—*New Northwest*, July 17: Mr. W. A. Koneman, with W. A. Rodgers as general manager, has just completed the erection of a quartz mill near the old town of Reynolds City, on the northeast side of the range that divides Elk creek from Deep and Bear gulch, and just below the mine called the Happaranda, lately purchased by Mr. Koneman for \$25,000—\$3000 being paid down and the balance in installments. The mine was discovered 13 months ago and two tunnels run in on the lead 140 and 100 feet, with shaft connections to the surface, and about six feet width of lead and free-milling gold ore, but may be of low grade. The mill consists of a rock-breaker and a small pulverizer, made almost like a blower used in a blast furnace, inside of which four iron shoes revolve 1700 times in a minute, and so great is their pulverizing properties that they soon wear out, but can be replaced in 15 minutes. Their capacity is said to be 25 tons per day. There are four amalgamating pans and two concentrators, capable of working 100 tons per day. Mr. Koneman is the inventor, and claims a superiority over all others, the principal advantage being an easily adjusted motion, and the concentrates being carried up-hill on four-foot rubber rollers with a scraper underneath, while the tailings are washed down the incline into a settler. About a ton of concentrates that assayed \$114 per ton were saved in a 30 hours' run, a result he claimed not attainable by another process. No cleanup had yet been made. The placer mines at the head of the gulches will soon close down for want of water. There are more Chinamen working in the gulches than there has been for the past two years, and it is thought to be on account of their being driven from other places. Messrs. David Allen, Nat. Preston and Mr. Smith, of Butte, are prospecting with reported success upon the divide between the top of Deep and Bilk gulches.

## OREGON.

**QUARTZ AND PLACER.**—*Jacksonville Times*, July 23: L. D. Brown's mill has resumed crushing ore from Swinden's ledge. The past season has been a better one for placer miners than several past. There is considerable stir in mining circles, notwithstanding the hot weather. Gin Lin is still piping at his mines near Uniontown, but will make a cleanup before long. Piping has been suspended at McCall & Anderson's mines, two miles this side of Ashland. Patterson & Co., who are mining on Grouse creek, in the Siskiyou, are doing well this season. Lance, Duffield & Co., of Foot's creek, are finishing up and have done very well this season in their placer claims. Wimer & Sons, of Waldo, are cleaning up their season's work, and no doubt their big mine has paid them as well as ever. Two different parties have offered to put up a mill on the site of the Hope ledge, in Wagner Creek district, which prospects well. A party consisting of Messrs. Dollabride, Smith, Hawkins and Barnes, are opening a new placer mine on Beaver creek with good prospects. A number of mining operations on an extensive scale will soon be inaugurated in Josephine county, which offers superior inducements to placer miners. Blalock, Owings & Co. are still engaged in pulverizing cement at their claim on Jackson creek with sledges and washing the pulp in a rocker with good results. The Eureka Mining Co. is testing quartz from its ledge in Willow Springs precinct by means of an anastra, which crushes 600 pounds of quartz daily, with favorable results. The shaft now being sunk on the Wagner Creek Mining Co.'s ledge, known as the Pilgrim, has reached a considerable depth, and the ore shows considerable of an improvement. Baunle, Klippel & Co. have broken ground for their new quartz mill on Shively gulch, and mean business. Mr. Klippel will leave for Portland and San Francisco soon to obtain more machinery. J. N. Casteel is finishing up his contract with the Jacksonville Milling and Mining Co., but finds the rock quite hard and progress slow. He has commenced running a tunnel to tap C. C. Beekman's ledges. G. B. Caldwell & Son are cleaning up at their mines on Steamboat, and are doing quite well. Finney & Prickett are also taking out considerable gold, although they were compelled to abandon their hydraulic pipe and use picks and shovels, owing to the deepness of their diggings. Messrs. Cornelius, Church and Hastings, of Portland, who purchased H. Wines' placer mines on Jump-off-Joe, are now in this section making preparations for next season's run. They will put in a hydraulic pipe and a giant and operate on an extensive scale. These gentlemen are also interested in one or more quartz mines in Josephine county. Thirty tons of ore from B. A. Knott's ledge in Willow Springs precinct was crushed in L. D. Brown's mill near the Swinden mine recently, and turned out well. It is said that the quartz averaged \$10 a ton.

## UTAH.

**REVIEW.**—*Salt Lake Tribune*, July 24: The receipts of ore and bullion in this city for the week ending July 21st inclusive, were \$206,214.59 in the aggregate, of which \$57,739.10 was ore and \$138,475.49 was bullion. For the previous week the receipts of bullion were \$117,172.92; of ore, \$73,572.98; of both, \$190,745.90. The Ontario product for the week was 22,147.93 ounces of fine bullion, and \$14,302.72 in ore sales. The Daily shipped 18,171.19 fine ounces during the week, 13 bars. No ore sales. Fine bar receipts for the week amounted to \$40,347; base bullion, \$21,350. The product of the smelters for the week was as follows: Hanauer, \$27,585; Germania, \$15,501.87; Pascoe, \$2915. The Stormont sent up silver bars to the value of \$3350. The Alice sent down 30 bars of bullion during the week, \$25,127.62. Ore receipts during the week were: By Wells, Fargo & Co., \$21,579; by McCornick & Co. (including \$8265 Queen of the Hills), \$25,265; by T. R. Jones & Co., \$20,894.10.

GET THE BEST.

## The BARAGWANATH

### STEAM JACKET FEED WATER HEATER AND PURIFIER.

Adapted to High &amp; Low Pressure Engines.

OVER 5000 IN USE.

The advantages of this Heater, briefly stated, are as follows: It loses no heat by radiation. That portion of the water chamber which in all other heaters is subject to the cooling action of the atmosphere is converted into a heating surface by the Steam Jacket.

It has twice the heating surface of any other of equal size.

It delivers its water always above the boiling point, averaging from 215 degrees to 220 degrees. By boiling the water under pressure all impurities are thrown off.

It keeps the Boiler clean and free from scale, by which means a large saving in fuel is effected, as also a great saving in repairs, as well as the capacity of the Boiler largely increased.

It never causes any back pressure on the Engine, but acting as a surface condenser relieves any back pressure that may exist. Send for Circular.

A. P. BRAYTON, Jr.,  
Agent for the Pacific Coast.

PACIFIC IRON WORKS,  
127 First St., San Francisco, Cal.

## THE BARAGWANATH HEATER.

WHAT IS SAID OF THEM BY PARTIES USING THEM.

"Heats water to 220 degs."

St. Louis, Mo., August 24, 1885.

Messrs. Wm. Baragwanath & Son, Chicago, Ill.—GENTLEMEN: We take pleasure in informing you that your Steam Jacket Feed-Water Heaters have given perfect satisfaction. We work the same in connection with three batteries of boilers, representing 650-horse power. They heat the water to 220° Fah., and we warmly recommend them to all establishments using steam machinery. Yours truly,

ANHEUSER, BUSCH BREWING ASS'N.  
GEO. KRUMSICK.

WOODMAN LINSERD OIL WORKS,  
OMAHA, NEB., Dec. 21, 1885.

Messrs. Wm. Baragwanath & Son, Chicago, Ill.—GENTLEMEN: Your heater is working to our perfect satisfaction. Temperature of feed-water is 218° and purification is perfect. From all appearances the heater is in perfect condition. It has been in constant use for three years. Yours truly,

CLARK WOODMAN, Pres.

Chicago, Dec. 15, 1885.

Wm. Baragwanath & Son—DEAR SIR: In answer to your favor of the 11th inst., we beg to state that we have purchased a large number of your Heaters for use of mining companies in the West and foreign parts. We have always received the highest possible testimonials regarding the operation of the Heater, and personally, we consider it equal to any Heater in the market, and give its use preference at all times. Yours truly,

FRASER &amp; CHALMERS.

GET THE BEST.

## THE BARAGWANATH HEATER.

WHAT IS SAID OF THEM BY PARTIES USING THEM.

Saves a ton and a half of Coal per day.

F. MAYER &amp; Co.,

Manuf'rs Furniture, 300 to 341 S. Clinton St.,  
CHICAGO, August 28, 1880.

Mr. Baragwanath—DEAR SIR: We have been using your Steam Jacket Heater for several months, and find it fully up to your representations. It saves us about a ton and a half of coal per diem, and gives us a regular steam pressure. It works to our entire satisfaction in every respect. Yours respectfully,

F. MAYER &amp; CO.

## PULLMAN PALACE CAR CO.

PULLMAN PALACE CAR WORKS,  
DETROIT, Mich., Feb. 25, 1882.

I beg to report the Steam Jacket Feed-Water Heater and Purifier, made by Baragwanath, of Chicago, has been in operation in our works for some time, and from careful test I find the heat of feed-water delivered from Heater 215 degs. Fah. I do not find any visible back pressure on the engine. The engine had eight pounds of back pressure when working in connection with our old Heater. We save 30 per cent in fuel, and one fireman. We have dryer and hotter exhaust for warming shops than before. I also find the Heater the best apparatus for removing scales I have ever seen.

CHARLES MERRY, Chief Engineer.

GET THE BEST.

## THE BARAGWANATH HEATER.

WHAT IS SAID OF THEM BY PARTIES USING THEM.

"Boiler Clean as Possible."

OFFICE OF CHAS. FIGLER,  
Manuf' of Flour, Feed and Meal,  
NEW AUBURN, MINN., March 11, 1882.

DEAR SIR: In response to your inquiry about the working of the Baragwanath Heater I bought of you last summer, would say it is the best Heater and Water Purifier to my knowledge. I would not be without it for twice its cost. My boiler is as clean and free from scales as it is possible to be, and I invite steam users contemplating to buy a Heater to come to my mills and examine mine before they buy elsewhere.

Respectfully yours, CHAS. FIGLER.

STANTON, MICH., March 17, 1881.

Wm. Baragwanath—DEAR SIR: After two years' use of the Heater, we can say your guarantee has been fully met. It delivers its water into the boiler at 217 Fahr., purifying it to a very great degree, and saving fully 20 per cent of fuel. No new scale has formed on the boiler since its use. It is a success, and the best Heater we have any knowledge of. Yours truly,

TURNER & REYNOLDS.  
October 30, 1885. Does all it ever did; never had a cent's repairs; know of nothing which equals it.—T. & R.

DETROIT LINSERD OIL COMPANY,  
DETROIT, Nov. 24, 1885.

Wm. Baragwanath & Son, Chicago—GENTLEMEN: We are using your Steam Jacket Heater and Purifier with great satisfaction, obtaining at all times the best results. Yours truly,  
SAM'L E. PITTMAN, Manager.

## IMPORTANT TO GOLD MINERS!

### SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.  
BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.  
E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

WILLIAM H. TAYLOR, President.

R. S. MOORE, Superintendent

L. R. MEAD, Secretary.

 345,797.—REVERSIBLE PLOW—Neil McLean, Watsonville, Cal.  
 345,804.—SEWER-CLEANING APPARATUS—Geo. W. Pringle, Benicia, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

## Mining Share Market.

Work is going on actively at most of the Comstock mines, though two of them shut down this week for repairs. Stocks, however, have shown no special activity. The lateral drift north from the Combination shaft, 3200 level, to connect with the drift coming south from the bottom of the Hale and Norcross deep winze, has been driven ahead at a very lively rate. It is skirting along the east side of the fine ore vein developed at the west face of the station, and the last 20 feet has grazed into the vein itself on the west side of the drift, showing some very good ore—better than was found in the west face of the station itself. Connection with the deep-winze drift will probably be made to-morrow, if not sooner. After the drift is properly straightened up, crosscutting west will be in order, and the true value of the ore vein be made practically manifest. The water is well reduced in the Osbiston shaft, ready for deeper sinking, and the Combination shaft still deeper is all right in that respect. In fact the middle and northern section of the Comstock is under good drainage subjection and amply prepared for deeper explorations, but no assistance is given from the south end—the Gold Hill mines. The *Enterprise* says: The Combination shaft being down to below the 3200 level, drains a very considerable of the country south belonging to the Gold Hill sections, and it is but just that the Gold Hill mines should now join in and assist in the good work. The Yellow Jacket new shaft could be utilized to most excellent advantage in this respect, being 3000 feet in direct vertical depth with the pumps, which were taken out when the mines were flooded four or five years ago, ready to put in again, and ample surface machinery for pumping or sinking a thousand or two feet deeper.

## New Incorporations.

GEM CONSOLIDATED CO., July 23. Location Trinity Co. Capital stock \$1,000,000. Directors, Geo. F. Geise, W. H. Sharp, A. D. Allen, D. Puck and J. A. Steinberger.

MORGAN OYSTER CO., July 23. Object to cultivate and deal in oysters. John S. Morgan, John Crellin, Thomas Crellin, J. Arthur Crellin and Fred. C. Morgan are the directors. Capital stock \$500,000.

MERRIMAC PLACER M. CO., July 24. Location Marble creek, Butte and Plumas counties. Capital stock \$20,000. Directors, F. J. McWorthy, Hank Small, J. Billington, L. T. Farr and O. V. Harvey.

BARDETT M. CO., July 25. Capital stock \$25,000. Directors, Jay Deming, Leon Maison, M. T. Frietas, John J. Wall and A. Bardett.

AMERICAN CRACKER CO., July 27. Capital stock \$200,000. Directors, Leon Sloss, James H. Jennings, John Proctor, James Dunn and George H. Garthorne.

FIREMAN'S FUND INS. CO. The directors of the Fireman's Fund Insurance Co. have notified the Superior Court of an increase of the company's capital stock from \$750,000 to \$1,000,000.

## Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Margat Ann, July 21, \$1648; Oro Grande Mill, 25, \$1521; Alice, 16, \$10,596; Hanauer, 17, \$3270; Germania, 17, \$1858; Hanauer, 21, \$3095; Queen of the Hills, 21, \$2095; Germania, 21, \$3907; Hanauer, 23, \$3100; Pascoe, 23, \$1550; Germania, 28, \$1074; Hanauer, 23, \$10,720; Crescent, 23, \$5920; Hanauer, 24, \$31,601; Queen of the Hills, 24, \$3105; Germania, 24, \$2022; Alice, 16, \$10,596; Queen of the Hills, 23, \$2695; Alice, 19, \$14,533. Last week Wells, Fargo & Co., at Salt Lake, received in bullion \$85,576; McCornick & Co., \$59,115; T. R. Jones & Co., \$35,395; Union Bank, \$25,127. The banks of Salt Lake City report the receipt for the week ending July 21st, inclusive, of \$138,475.49 in bullion and \$67,739.10 in ore, a total of \$206,214.59.

## New York Metal Market.

Telegraphic advices dated July 29th give the following New York prices:

BORAX—63 1/2 @ 7 1/2 c.  
 BAR SILVER—94 per oz.  
 COPPER—LAKE—\$10.00.  
 IRON—No. 1, \$17 @ \$18.00; No. 2, \$15 @ \$16.00.  
 LEAD—\$4.85 @ 4.95.  
 QUICKSILVER—43 @ 43 1/2 c. per lb.

The following is the latest by mail from the "New York Metal Exchange Market Report":  
 COPPER—Neglected; Lake offered at 9.90c @ 10.00c. Transferable Notices (Lake) offered at 10.00; Transferable Notices (Chili Bars) offered at 10.39.

LEAD—Nominal at 5.00 @ 5.10c. Transferable Notices (Domestic) issued at 4.95.

TIN—Firm, closing at \$21.85 @ \$21.90. Transferable Notices issued at \$22.10c.

SILVER—New York, 95% per oz. London, 43 1/2 d. MAKER'S PRICES—At tidewater. too ton lots of listed irons (when brand is specified) range nominally about as follows: Lehigh, Grade No. 1, \$18 @ \$18.50; No. 2, \$17.00 @ \$17.50; Grey Forge, \$15.00 @ \$16.00. Hudson River, Grade No. 1, \$18 @ \$18.50; No. 2, \$17.00 @ \$17.50; Grey Forge \$15.00 @ \$16.00. Southern, Grade No. 1, \$18.00 @ \$18.50; No. 2, \$17 @ \$17.50; Grey Forge \$15 @ \$16.

Prices generally ruling for metals not regularly dealt in on call at the N. Y. Exchange, covering extremes of buyers' and sellers' views. All prompt delivery.—Australian Tin, \$21.80 @ \$22.00; Billiton Tin, \$22.40 @ \$22.75; Banca Tin, \$22.60 @ \$22.90; Baltimore Copper, \$9.25 @ \$9.75; Orford Copper, \$9.25 @ \$9.75; P. S. C. Copper, \$9.25 @ \$9.75; Foreign Lead, \$4.90 @ \$4.95; Foreign Spelter, \$4.80 @ \$4.85.

## Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

## Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

JARED C. HOAG—California.  
 G. W. INGALLS—Arizona.  
 E. L. RICHARDS—San Diego Co.  
 R. G. HUSTON—Idaho and Montana.  
 GEO. McDOWELL—San Luis Obispo and Santa Clara Co's  
 FRANK W. SMITH—Idaho and Montana.

JULIUS REIMER has been admitted to practice as an attorney and counselor-at-law. He has had much experience in San Francisco as an expert accountant, and many years ago he was the editor of *The Engineer of the Pacific*.

## Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this Coast now for so many years, the firm's name is a well known one. Another reason for its popularity is that a great proportion of the Pacific Coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this Coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That this is understood and appreciated, is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (S. F.) from week to week and year to year.

## Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

MINERS and prospectors are going to Meadow Lake district. But as the process that is to work out the salvation of the place has not yet been practically proven a success, it seems rather early for an excitement.

MISFIT institutions bring grist to the mill. Muller's optical depot, 135 Montgomery St. x

## Books on Assaying.

By C. H. AARON.

## PART I.—Gold and Silver Ores.—Price \$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

## Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables. The volume embraces 106 12mo. pages, with illustrations, well bound in cloth; 1884. Price, \$1, postpaid. Sold by DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

## PARTS II AND III.

## Lead, Copper, Tin, Mercury, etc.

Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

## Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Manipulation, etc.; Lead Ores; Copper Ores; Volumetric Assays; Parkes' Process; Amalgamation; New Process; Preparation of Potassium Zanthate; Electrolytic Determination of Copper in Ores, etc.; Assaying of Tin Ores; Assaying of Mercury Ores; Assaying of Zinc Ores; Assaying of Zinc Ores, New Method; New Assay of Nickel and Cobalt; Assay of Chromium; Assay of Bismuth; Assay of Arsenic; Assay of Antimony; Assay of Sulphur; Assay of Salt; Appendix to Part I; Notes on Crucible Assays; Weighing by Oscillations; Appendix to Part III; The Assay of Lead; The Assay of Copper.

There are 160 12mo. pages with illustrations in the volume, which is bound strongly in cloth. Price postpaid, \$1.75. Sold by DEWEY & CO., Publishers, No. 252 Market St., S. F.

## Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise

**Practical Hydraulics.**

By P. M. RANDALL.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

**Table of Contents.**

The following brief abstract of the contents will give an idea of the branches of the subject treated:

General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulas Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated, and Expressed in Formulae and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water Over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow Through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water Through Short Tubes and Compound Tubes; Flow of Water Through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow Through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by Dewey & Co., Publishers, 252 Market St., San Francisco.

**Practical Treatise on Hydraulic Mining**

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For sale by Dewey & Co., Publishers, 252 Market St., San Francisco.

**DIVIDEND NOTICE.**

OFFICE OF THE

**Paradise Valley Mining Company**  
San Francisco, California.

At a meeting of the Board of Directors of the above named Company, held July 26, 1886, Dividend No. 7, of twenty-five (25) cents per share, was declared, payable immediately at the office of the Company.

W. LETTIS OLIVER, Secretary.

OFFICE—No. 328 Montgomery Street, San Francisco, California.

**FOR SALE.**

Half Interest in Patent Right and Manufacture of the finest Quartz Breaker and Pulverizer of the age.

Machines in operation and subject to any test.

Call on C. G. Y., at office of DEWEY & CO., 252 Market Street, San Francisco.

**THE RUSSELL PROCESS COMP'Y.**

C. A. STETEFELDT, President.

NEW YORK OFFICE, 18 BROADWAY  
Room 709.

**THE ROLLER ORE FEEDER**

(Patented May 28, 1882.)

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repairs.

## ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—

**SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE  
DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.**

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

OFFICE, 404 MONTGOMERY STREET, SAN FRANCISCO.

**HOOD'S FOUNDRY COKE.**

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

# \$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,  
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.**  
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street.

SAN FRANCISCO, CAL.

# \$1,000 CHALLENGE ACCEPTED, PRICE, FIVE HUNDRED AND FIFTY DOLLARS (\$550.00).

**THE  
"TRIUMPH" ORE CONCENTRATOR.**

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE, placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

## DAMAGED BY FIRE!

Engines, Boilers, Wood and Iron Working Machinery, Belting, Etc.

### FOR SALE CHEAP!

The fire which destroyed our building, Nos. 25 to 31 Main Street, on the 20th of June, will have no effect on our business.

We have already secured one of the stores in the magnificent Donahue Block, Nos. 34 and 36 Fremont Street, near Market, the finest in the city.

We have removed our Machine Shop to Nos. 225 and 227 Beale Street, and are now in full blast.

Our Oil Warehouse is located at 519 Front Street.

Our Oregon Branch is still at 91 and 93 Front Street, Portland.

Constant arrivals of new stock will enable us to supply our customers with everything of the latest and best description.

In addition, we shall have all of our old stock of Machinery, much of which had just come in, removed from the burnt building to our new store, where we shall be able to offer it at **EXTREMELY LOW PRICES.**

When the fire occurred, we had, fortunately, finished shipping the mammoth mills for La Trinidad and Silver Queen Mines, of Mexico, and the 20-Stamp Mill for the Buchanan Mine, of Tuolumne.

Notwithstanding our fire, the Pacific Lumber Company, of Humboldt, awarded us the contract for their new mill over all competitors, preferring to wait till our New Shop was ready rather than get their Machinery elsewhere, though they are in a great hurry. We consider their action conclusive evidence of the superiority of our Machinery, as they are determined to have the finest mill on the Coast.

Our New Concentric Set Works and Headblocks, and the Sinker, Davis & Co. Band Log Mill, which we recently furnished the Humboldt Lumber Company, of Humboldt, are pronounced by them superior to any ever seen in Humboldt.

We are now at work on nine Headblocks for Pope & Talbot Mills on the Sound.

From the above facts, it would appear that we stand fire pretty well, and if our patrons will kindly continue to favor us with their valuable business, we will do our best to excel our former efforts.

**TATUM & BOWEN, San Francisco and Portland.**

## The Pneumatic Pulverizer.

A new principle of pulverization of quartz consists in the employment of two powerful opposing currents of dry, superheated steam or air, so arranged and adjusted that they continuously charge themselves with crushed or granulated material, and by the great force and velocity of the steam currents the minerals are dashed against each other with such power of concussion as to cause the hardest ores to be pulverized to an impalpable dust. This principle has been established by pulverizing one of the most difficult ores (chrome iron) continuously for many months. The high temperature of the superheated steam currents employed, through which every minute particle of ore must pass, causes them to become very hot and dry, which produces, it is claimed, a beneficial effect on sulphurets and ores containing rusty gold.

We give on this page engravings showing a complete plant of four pulverizers with elevator, and jet exhaust connections, the superheater, and the boiler; also a sectional view showing opposing currents. The wearing parts in this device are two very small tubes of hard cast iron, weighing one pound each, which can be removed and replaced in a few minutes. The plant is complete within itself, only requiring a level floor to stand upon, and when in full working operation is almost noiseless, and free from escaping dust. Damp ores that can be crushed

sired, ranging from a coarse sand to an impalpable powder. It can be arranged to discharge into a tank hot and wet, if desirable.

The company furnish (in all cases) a boiler,

Section Showing Air Currents.

verizer Co., Nos. 2 and 4 Stone street, New York, are prepared to furnish complete plants of 10, 25, 50, 75, 100 or 200 tons per day, including a sectional steam boiler, supplying all the power required to work the pulverizers to their full capacity. The pulverizers are all made the same size. For large plants larger boilers are provided, and pulverizers sufficient to do the work are added. In addressing the company, requesting price for plants, persons should forward an average sample of the ore, state the degree of fineness they desire, and the quantity they wish to pulverize per day of 24 hours. They will then be able to give a price, either in New York or complete at the mine or works, that will do the required work. Several persons who have used this pulverizer testify to its efficiency.

## Tuesday's Pageant.

A more sublime spectacle than the grand parade and review on Tuesday has never been witnessed in San Francisco. The Knights Templar parade of 1883 was more gorgeous in symbolism and showy regalia, more brilliant in military evolutions, but never were the streets crowded with such a vast mass of eager humanity, made more sonorous with bursts of martial airs, and the sight of the old grizzled veterans of the war, with their bullet-riddled flags, awoke sentiments of gratitude and admiration akin to those of religion in sacredness. All the prin-

## Foundry Notes.

The men who went out of the boiler shop of the Risdon Iron Works a few weeks ago, at the order of the Federated Trades, because they were put at work on the boilers of a steamer managed by a firm that had been "boycotted," have sensibly made up their minds to go back to work. They had no complaint about wages, hours, or anything of that kind, and the strike was a foolish one. At a meeting of the Iron Trades Council on Saturday night, resolutions were adopted recommending that the boiler-makers who left the Risdon Iron Works three weeks since disregard the action of the Trades Federation and return to work. The boiler-makers then held a meeting and decided to go back to work, which they have done. Next morning 110 of the strikers appeared at the shop and were told by the foreman to resume work if they desired. This they did, and everything is running as smoothly as though nothing had happened. It is stated that at the last meeting of the Trades Federation it was understood that if the steamer *Alameda* sailed with non-union men a special meeting would be called and the Spreckels boycott declared off. The *Alameda* sailed on Saturday with a non-union crew, so on Monday evening, at a meeting of the boiler-makers, they concluded to act for themselves, with the result as stated.

The molders have withdrawn from the Federated Trades, and it is now said that the boiler-

COMPLETE PLANT OF PNEUMATIC ORE PULVERIZERS, WITH BOILER, SUPERHEATER, ETC.

so as to feed freely into the pulverizers, need no previous drying. The ores require crushing and should pass through a quarter-inch mesh screen before entering into the pulverizer, after which the operation is automatic and continuous, requiring but little attention.

Two men, including fireman, can attend a plant of 50 tons pulverizing capacity per day. A dry steam jet is employed to exhaust or draw the pulverized material from the machines and deposit it in a dust chamber. This jet can be adjusted to throw the pulverized material into the dust chamber at any degree of fineness de-

superheater attached, to supply the pulverizers with steam, of ample capacity and pressure.

The boiler is constructed of tubes of small diameter, with metallic joints and fittings, insuring the greatest possible strength and durability with absolute safety. When erected for use it is tested and proved to sustain a pressure of 500 pounds to the square inch, although the pulverizer only requires a working steam pressure of about 200 pounds.

The pulverizer will crush gold and silver ore, iron ore, cement, phosphates, etc., to any required degree of fineness. The Pneumatic Pul-

verizer Co., Nos. 2 and 4 Stone street, New York, are prepared to furnish complete plants of 10, 25, 50, 75, 100 or 200 tons per day, including a sectional steam boiler, supplying all the power required to work the pulverizers to their full capacity.

The figures of Washington, Lincoln, Garfield and other noted soldiers were seen everywhere, together with battle-pieces, camp scenes, soldiers on picket duty with such inscriptions as "Welcome," "Welcome to the Brave," "Welcome to California." To one looking up Market and Kearny streets the flags, streamers and pennants seemed to cover the streets. The superb triumphal arch on Market street added greatly to the imposing occasion; for elaborateness and beauty of historic designs it has probably never been surpassed on the continent.

makers and other iron-workers' unions will do the same at the next meeting.

The Iron Trades Council has appointed a committee of four to wait on Governor Stoneman and request that the work to be done on the fireboat *Governor Irwin* be not given to the Union Works. The strike at these shops still continues.

THE Eartlick Bros., of Oro Fino, Siskiyou county, shipped \$25,000 (in gold dust) to San Francisco, which is the result of their season's run.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—EDS.

## Marysville Mines, Montana.

EDITORS PRESS:—The mineral belt of which this embryo city is the natural depot is about three miles wide by six miles in length. There are other paying districts lying outside of these boundaries which contribute to this place.

Marysville is 20 miles northwest of Helena, the capital, and is reached by a good wagon road, over which three daily lines of stages run.

The Montana Central Railroad is grading its road-bed thither, but it is not known when the rails will be laid on account of the high price demanded by the U. P. railroad for hauling the same from Duluth to Helena.

The Drum Lummon mine is located here, and as this letter is only intended as introductory, I shall not attempt to describe this magnificent property until some subsequent time.

One-half mile west is the Belmont—a good gold-bearing mine with a mill of 30 stamps, but idle from some cause or other.

Two miles west is a group of gold-bearing lodes, principal among which are the Bluebird and Hickey. A 10-stamp mill on this property has produced fortunes for the owners.

Two miles southwest from this point lies the Bald Butte group, owned by Helena men. A 10-stamp mill keeps busy, and pays well during the summer months. A five-stamp mill is also located here, which has paid its owners handsomely.

Three miles northwest from Marysville lies the Empire mine, recently purchased by English capitalists for \$80,000, which is considered a very great bargain. Development is progressing rapidly, and a 10-stamp mill is kept busy.

Near here is the Gloster, which has produced wonderfully in the past five years; it has 60 stamps in operation. The Penobscot, near Bald Butte, should not be forgotten, as it is the lead Nate Oestel sold in 1878 for \$400,000. It was worked for two years by an Eastern company, and just paid expenses. John Longmaid purchased the property last August with the 10-stamp mill thereon, and it is estimated has cleared \$50,000 out of what the imported Eastern superintendent left in sight.

The number of stamps in the district is as follows:

Belmont.....	30
Mount Pleasant.....	10
Bald Buttes.....	10
Edge & Wormer.....	5
Penobscot.....	10
Empire.....	10
Gloster.....	60
Drum Lummon.....	60
<b>Total.....</b>	<b>195</b>

The Drum Lummon Co. are now erecting 60 additional stamps, and a one-stamp pony mill is at Marysville, which by October 1st will make a total of 256 stamps. The Empire Co. will greatly increase their milling plant, but probably not before next spring.

The Union Iron Works of San Francisco have placed several hundred tons of excellent machinery in the district at the Drum Lummon and Gloster.

There are any number of good mines here that need the energetic Californian to examine, so we will get some of those thorough mining men in this district.

Marysville, M. T.

## Mining Safety Cages.

H. W. Bracken writes to the *Virginia Enterprise* as follows: Having read in some of last week's *Enterprises* the practical views expressed by gentlemen from Silver City and Bodie, relative to the most practical and effective style of safety devices for cages in mining shafts, for the prevention of the many sad and fatal accidents such as have occurred in times past, through the breaking or non-breaking of the cable, I would like to make a few pertinent remarks as a mechanic and miner. I have considered carefully their views on the subject and approve of them to the extent of their merits. I take occasion, however, to state that I also have a device of my own invention, the result of careful study of every phase and result of the proposition, which I confidently submit to the practical mining mechanics, engineers and superintendents of the Comstock or anywhere else.

It is simply a safety clutch, which is absolutely obliged to work automatically in case of cable breakage, unlatching of the reel or any other of the fatal circumstances or conditions heretofore encountered in that line, and to prove my knowledge, earnestness and perfect confidence in the matter, wherein so many human lives have been and still are at stake, I will unflinchingly offer the following test:

Place a single or double deck cage on the chairs at the surface or top of the shaft, unlatch the reel to spin around its axles freely and as lively as possible, slacking down all the cable you please between the reel and the sheave, or between the sheave and the cage, or take off the cable altogether, or keep on the cable at any sort or degree of tension, and, regardless of the present style of very eccentric safeties, with my own invention as a safeguard,

I will step upon the cage, with my hands in my pockets, and allow the chairs to be pulled back, betting anybody \$1000 that the cage will not drop 12 inches.

This may seem like a foolhardy proposition, but I know what I am talking about, and any true mechanic or practical mining engineer who examines critically my device must simply understand and see that I am right, and that the same demonstrative experiment may be performed with perfect safety at any point in the shaft as well as at the surface.

Bear in mind that all the fatal mishaps referred to have occurred through the failure of the safeties to work with a tension on the king-bolt. My device is totally regardless of either tension or king-bolt, and any interested parties, who may feel skeptical in the matter, are freely and confidently invited to inspect my invention and accept my offered test.

[With reference to the foregoing communication, we will state that we have by invitation examined a working model of Mr. Bracken's device. Square wings, compactly situated and very sensitive in action, cause the eccentric clutches or safeties to promptly act upon the guides in case of any undue speed of the cage downward from the breakage, unlatching or unreeling of the cable. These wings can be placed beneath or above the cage, but their action is certain, causing not only the safeties connected with them to act, but obliging the old style of safeties which may be attached to the cage also to act. Thus a two-fold safety is secured not only to human life but for costly mining cages, cables and other accompanying property. The device needs but to be seen to be appreciated. It certainly would cost but little for any of our mining companies to try it.—*Rep. Enterprise.*]

## Mining Dividends for the Half Year.

The New York "Financial and Mining Record" apportions the dividends of American mines for June and for the first six months of the year as follows:

	For June.	Jan. 1 to June 30.
New York.....	\$142,250	\$1,069,250
Boston.....	780,000	780,000
San Francisco.....	180,000	847,300
Elsewhere.....	316,500	1,054,647
<b>Totals.....</b>	<b>\$688,750</b>	<b>\$4,351,197</b>

These dividends have been disbursed by 43 mines, located in 11 States and Territories, as follows:

California.		
	Dividends.	Amount.
Derbec Blue Gravel.....	4	\$40,000
Mono.....	1	12,500
Plymouth Consolidated.....	5	125,000
Plumas Eureka.....	1	33,156
Sierra Buttes.....	1	30,625
Young America.....	5	80,000
<b>Totals.....</b>	<b>17</b>	<b>\$323,281</b>

The Derbec Blue Gravel is in Nevada county. This mine did not pay in January or May. The Idaho quartz mine, in the same county, is understood to have paid a dividend every month this year, but the "Record" has omitted it, probably owing to the refusal of the owners to report their dividends to the press. The Mono mine is in Mono county, and this is the first dividend. It was paid in March. The Plymouth Consolidated is in Amador county, and is credited with dividends for the first five months, though our record is only for four months. The Plumas Eureka and Sierra Buttes are owned in London, where the semi-annual dividends were paid last April. The Young America is in Sierra county. It is possible that these are not the only California mines that have paid dividends this year. Owners in any omitted mines who have received dividends this year have only themselves to blame for want of suitable credit in this particular. The *Bulletin* has always been glad to publish news announcements of this character.

Nevada.		
	Dividends.	Amount.
Con. California and Virginia.....	1	\$64,800
Holmes.....	3	75,000
Jackson.....	3	15,000
Manhattan.....	2	25,000
Paradise Valley.....	1	10,000
Richmond, Con.....	1	67,500
<b>Totals.....</b>	<b>11</b>	<b>\$257,300</b>

The above is the first dividend of the Consolidated California and Virginia since the two mines were merged under that corporate title. It was paid in February, at the rate of 30 cents per share. The Holmes paid its first three dividends in February, March and April. We understand that the dividends were suspended because of the low price of silver, and not because of a want of silver-bearing ore, of which, we are told there is an abundance. In addition to the dividends paid by the Jackson mine in January, March and June, there was a stock dividend of 10 per cent in March. The two dividends by the Manhattan mine were paid in January and February, and the one by the Paradise Valley in February. Both have paid dividends before, and both are well supplied with silver-bearing ore.

Utah.  
The Ontario Mining Company paid six dividends of \$75,000 each, or \$450,000 in the half year, despite the fact that the mill was closed down for nearly a month.

Idaho.  
The Idahoan mine is not incorporated. The owners claim to have divided up \$60,000 among

them, in four installments, in the half year, or 31 per cent of the net proceeds.

Dakota.		
	Dividends.	Amount.
Caledonia.....	2	\$20,000
Homestake.....	6	300,000
Iron Hill.....	6	75,000
<b>Totals.....</b>	<b>14</b>	<b>\$395,000</b>

The dividends of the Caledonia were paid in January and February. A cave in the mine followed. The debris has since been removed, and there is a prospect of an early resumption of dividends.

Arizona.  
The Silver King Mining Company has paid six dividends in the half year, amounting to \$150,000. There is not another mine in the whole Territory that has paid a dividend this year, so far as we can learn.

New Mexico.  
The Peacock Mining Company is reported to have paid its first dividend of 5 cents per share, or \$10,000, in June. The office of the company is at St. Louis, where the dividend was paid.

Mexico.  
We know no mines in Mexico that have paid dividends this year. Even the Jucustita has ceased to remember stockholders. The low price of silver is hard on the Mexican mines, whose product is almost exclusively silver.

Montana.		
	Dividends.	Amount.
Alice.....	1	\$25,000
Boston and Montana.....	6	180,000
Elkhorn.....	6	30,000
Granite Mountain.....	6	520,000
Hecla Consolidated.....	6	90,000
Helena Mining and Reduction.....	1	18,000
Moulton.....	1	30,000
Montana.....	1	128,750
<b>Totals.....</b>	<b>28</b>	<b>\$1,016,750</b>

The mines of Montana are being worked on close business principles and with encouraging success. The Montana was formerly known as the Drum Lummon, and is owned in London. An interim dividend of 62½ cents per share, or \$207,600, was paid on the 15th of July, making \$620,000 to date.

Colorado.		
	Dividends.	Amount.
Adams.....	6	\$105,000
Colorado Central.....	3	42,500
Freeland.....	2	40,000
Hubert.....	2	16,116
Iron Silver.....	1	100,000
Plutus.....	1	20,000
Robinson Con.....	1	24,000
Silverton.....	6	437,500
Small Hopes.....	6	212,500
Yankee Girl.....	6	212,500
<b>Totals.....</b>	<b>34</b>	<b>\$1,007,616</b>

The last dividend of the Freeland and Iron Silver was in April, and Robinson Consolidated in March. The Plutus paid its first and only dividend last February. The Mary Murphy paid its first dividend of 5 per cent last May; gross amount not known.

Michigan.		
	Dividends.	Amount.
Atlantic.....	1	\$40,000
Calumet & Hecla.....	1	500,000
Central.....	1	40,000
Franklin.....	1	40,000
Quincy.....	1	160,000
<b>Totals.....</b>	<b>5</b>	<b>\$780,000</b>

These are all copper mines, and the above dividends were paid last January and February. The Calumet & Hecla and Franklin have paid further dividends this month.

New Hampshire.  
The Valencia Mica Company paid a dividend of \$2.50 per share, or \$3750, last April, making \$37,300 to date.

Comparative Summary.  
Following is a summary of the dividends from incorporated mines for the six months ending June 30, 1886, compared with the same time last year:

1885.		1886.	
Mines.	Amount.	Mines.	Amount.
California.....	9	6	\$923,281
Nevada.....	4	6	257,300
Utah.....	3	1	450,000
Idaho.....	1	1	60,000
Dakota.....	3	3	395,000
Arizona.....	1	1	150,000
New Mexico.....	1	1	10,000
Mexico.....	2	8	1,016,750
Montana.....	5	6	1,007,616
Colorado.....	6	5	780,000
Michigan.....	2	5	780,000
North Carolina.....	1	1	40,000
Vermont.....	1	1	30,000
New Hampshire.....	1	1	3,750
<b>Totals.....</b>	<b>40</b>	<b>43</b>	<b>\$4,453,607</b>

For the same time in 1884, the amount paid in dividends was \$4,581,108 by 47 mines, against \$5,627,187 by 52 mines in the first half of 1883. Nearly one-half of the amount this year has been paid by the silver mines of Colorado and Montana.

Rowie's Mill in Six-mile canyon, below the Park mansion, is crushing ore extracted from the Ophir mine nearly a quarter of a century ago. This ore has been lying on the site of an old mill at Ophir, just north of Washoe City. Bullion valued at \$2400 resulted from a cleanup after crushing 26 tons recently brought to the mill by rail.—*Virginia Chronicle.*

The Nickel Company expect to commence operations on the nickel and cobalt mines at Lovelock, Nev., very shortly.

## Modern Inventions.

Their Multiplicity and Influence on the World's Material and Moral Progress.

How little the average man or woman stops to think how much of the ordinary comforts and conveniences of life are due to modern inventions. What would the housewife of to-day do without the thousand and one little "Yankee notions" which are now found in every kitchen? Even the cooking-stove and range are of quite modern invention. It is within the lifetime of all whom we now call aged that the old-fashioned fire-place with its crane, trammel and hooks, with a "Dutch oven" or baking kettle and a few iron pots were the only cooking utensils in use. The first stoves were merely cast iron boxes for heating purposes and not for cooking. Who to-day that has a family to sew for could think of doing without a sewing machine? Yet that almost indispensable household requisite is less than 40 years old.

What would our modern farmer do without the various descriptions of machinery with which the inventor of the present century has supplied him, in the way of harvesters, headers, thrashers, mowers, cultivators, harrows, etc.? By the use of these inventions the drudgery of farming has been transferred from the muscle of the farmer himself to that of his horses, and he has been enabled to reduce the price of his products to one-half and even one-quarter of that which he was formerly obliged to charge, to the great advantage of himself and the entire community which he supplies with so many of the necessities of life.

Again, go into the factory or the machine shop and witness the innumerable number of inventions, all calculated to lessen the toil of the human hand, reduce the cost of supplies of every kind, and add to the convenience and comfort of mankind. What a contrast between the machine shop 50 or 60 years ago and now! One hundred years ago the total number of steam engines in the United States could have been numbered on the fingers. In 1776—the year from which we date our independence—there were but three steam engines on the entire American continent! There is no need that we should speak of the power printing press, the railroad, the telegraph, the telephone, illuminating gas or coal oil. How could we do without either at the present time? Going back six or eight decades would seem to put us back 2000 years in the march of progress. It really would do so. For all the progress of the 2000 years in the mechanic and useful arts previous to the present century might be balanced by a single year of modern invention. The important influence which these inventions have exerted on the comfort, health and material progress of civilized nations needs no elaborate statement. But there is another direction of this influence of which little has been said or thought, but which is nevertheless real and of great importance. We refer to

## The Influence of Invention on Social and Moral Progress.

It is not in the mere physical or material directions alone in which the human family has been benefited by modern invention. Invention has accomplished a much higher and nobler work, in the advancement of the social, moral and religious condition of the world. This matter has been most pleasantly and profitably presented by a well-known mechanical engineer—Charles Talbot Porter, of New York—in a thoughtful volume recently published by G. P. Putnam's Sons. The work is entitled "Mechanics and Faith." To the majority of readers this title would seem to express the most opposite extremes of thought—the bringing together of subjects quite incongruous, and between which no relations could exist; yet the author, in discussing the power which he believes mechanical science is actually exerting, in guiding the development of thought and belief in moral truth, is really preparing the way for a still higher work in the direction of a philosophical system in which spiritual faith shall be fully recognized and honored.

According to our author, the peculiar adaptation of mechanical science and pursuits for this service is indicated in the claim that it exerts a healthful influence on thought, belief and morals, and, generally, on the spiritual nature of men. Concerning this influence, the author makes the following statement, that indicates the scope and object of the argument, which is both plausible and logical:

"It"—mechanical science—"is of a nature to aid directly in establishing in the mind the solid foundation of faith. Its immediate tendency is to dispel the idea of antagonism between reason and faith, to show that antagonism exists only between reason and credulity, and to vindicate the authority of faith over its own vast region. It shows that faith is consistent with the highest intelligence; that all true philosophy leads up to faith, and that the larger and more complete the comprehension of truth becomes the more absolute faith must become."

While we have neither time nor space to follow the author in his argument, we would briefly refer to the position taken in the outset, as stated by a reviewer in the following words: "This branch of science dealing as it does, not with matter, but with force, the unseen and eternal, is peculiarly fitted to carry the thought beyond things physical and visible. Force is

insisted on as a spiritual reality, and this fact is the key to the author's reasoning and the starting point of his argument. This leads to the conception of natural law, which, instead of being a substantive reality, can express nothing except the uniform mode of action of a Being, which is subsequently shown to be the uniformly beneficent action of a Being. In this view of force, bearing as it does against materialism, the author is probably in sympathy with Dr. Carpenter when he remarks, with reference to nature, that we should not speak of government by laws, but government according to laws, although Mr. Porter's conception more directly recognizes force as the divine energy. The materialistic views of nature are further combated in an argument against the atomic theory which is regarded as the bulwark of materialism. This discussion is interesting and able."

### Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

**STEAM COOKING APPARATUS.**—Daniel D. Mounts, San Francisco. No. 345,391. Dated July 13, 1886. This is an apparatus for cooking fruit by means of steam. The machine is complete in itself, embodying the source of heat, the steam generating water, the super-heating device and distributor by which the steam is discharged equally, and the receptacle containing the fruit jars.

**SEWER-CLEANING APPARATUS.**—George W. Pringle, Benicia, assignor of one-half to L. B. Mizner. No. 345,804. Dated July 20, 1886. An apparatus for speedily cleaning sewers is a very useful thing. This one consists of an endless chain extending down through the sewer, passing over guides and driving pulleys, and adapted to carry plows or scrapers, which travel through the material collected within the sewer, so as to loosen and remove it.

**CANDLESTICK.**—Samuel Tyrell, Grass Valley. No. 345,461. Dated July 13, 1886. This is one of that class of candlesticks in which a vertically adjusted rest is arranged within the main tube, whereby the candle may be raised and the grease discharged; and the invention consists in a rest having a fixed nut in its base, and in a screw passing through the base of the candlestick and threaded in the nut, said screw having a thumb-piece on its lower end by which it is operated. The object of the invention is to provide a candlestick in which the means for raising and lowering the rest are simple and effective and not liable to get out of order.

**ANIMAL EXTERMINATOR.**—Homer Esborn, Petaluma. No. 345,373. Dated July 13, 1886. This invention is one of that class of animal exterminators in which some combustible material within a cylinder is subjected to a blast of air, whereby the noxious fumes or products of combustion are driven out through suitable pipes into the hole or burrow of the animal; and the invention consists in the novel arrangement of the operating parts, and particularly in the independent nozzle which is inserted in the burrow and the exterior pipes connecting the nozzle with the combustion chamber, one of said pipes being shorter than the others, whereby sufficient ventilation is obtained.

**REVERSIBLE PLOW.**—Neil McLean, Watsonville. No. 345,797. Dated July 20, 1886. This improvement in reversible plows consists of a double landside and shares having a single double-faced mold-board hinged thereto and movable about the hinge, so as to serve as a mold-board for either share. The standard extends upward from the center of the landside, and is pivoted or journaled within the plow-beam, and has a circular disk turning against the lower surface of the plow-beam. In combination with this disk is a peculiarly-constructed holding and adjusting lever, and a means for swinging the double-faced mold-board from one side to the other when the plow is reversed.

**EXPANDING DRILL-BIT FOR ARTESIAN-WELL BORING.**—Chas. O. Lane, S. F. No. 345,385. Dated July 13, 1886. In artesian-well boring the drill-bit is passed down on the inside of the pipe until the cutting points project below, when it is rotated by suitable mechanism from above. In order to make a hole below the pipe larger than the pipe itself, the drill-bit is adapted to expand upon emerging from the pipe, but while passing down or up through the pipe it is in a contracted position. This is made possible by reason of the yielding or springy capacity of the legs; but it is obvious that after they have expanded some means must be used to hold them rigidly separated while at work, and to relieve them when about to be drawn up or lowered through the pipe. The main object of this invention is to provide simple and effective means to this end, and also to perfect the other portions of the tool. It is an improvement on a former bit made by the same inventor. It consists in two or more spring-legs, firmly secured at their tops to the head of the tool, their lower ends being formed into or provided with cutters, above which, on their outer surfaces, are formed peculiar or frictional bearing-knees; in a novel fixed or stationary fulcrum-block between the legs, over which they are adapted to bend when their lower ends are forced together, whereby the distance be-

tween the cutters is made shorter than the distance between the knees; in a novel adjustable automatic brace adapted to operate between the legs, to hold them rigidly separated when at work, and to release them when the tool has to be raised; in a beveled surface for the lower portion of the legs to guide and hold the brace and relieve its upper portion from undue friction; in a protecting and strengthening disk or flange on the head of the tool, a protecting rib on the upper portion of the legs, and certain details of construction which perfect the tool.

**PORTABLE HOUSE.**—Wm. J. Anderfuren, S. F., assignor of one-half to James Eva. No. 345,944. Dated July 20, 1886. The invention relates to that class of houses in which the parts are previously prepared in such a manner as to adapt them to be readily put together, and hence are generally known as portable houses. The invention consists in peculiarly grooved corner and intermediate posts having removable clamping plates or strips fitted to them; in siding having its ends prepared to fit the grooves of the posts and to be clamped therein by their plates, and its meeting edges tongued and grooved to form a novel overlapping dovetail joint with each other and the sills; in the window and door frames having dovetail tongues for fitting the dovetail grooves of the posts; in an outer top plate adapted to overlap the siding above; in an inner top plate or cornice adapted to overlap the siding on the inner side, and in various details of construction. The object of the invention is to prepare the various parts of the house so as to adapt them to be readily fitted together, at the same time fully providing for the subsequent adjustment of the house by taking up the shrinkage easily and effectually and concealing it, and also to provide for the change of a door or a window from one point to another, or the insertion of a new one.

**CHECK-REIN ATTACHMENT.**—C. L. Bard, San Buenaventura. No. 345,404. Dated July 13, 1886. This invention relates to that class of check-reins and hooks which enable the driver, unaided by any extra line or string in his hands, to check or uncheck his horse or horses at will by the action of the driving reins or lines alone, and without rising from his seat or leaving the vehicle. Mr. Bard has obtained several patents on this class of devices, in all of which the check-rein is attached to the driving lines or reins behind the plane of the pad, and is disengaged from the hook and re-engaged therewith by the action of said lines. The present invention consists in a check-rein in addition to the regular checking-slot of the first reins, a limiting-slot located back of the checking-slot, and acting as a limiting-check after the disengagement of the one in front, and in a check hook, the pivoted lever arm of which has in its rear end several openings or slots in different vertical planes, so that the check-rein may be adjusted to suit different sizes of horses and heights of vehicles, whereby, no matter what may be the relative position of the horse and driver, the perfect operation of the device may be had. The invention further consists in an improvement in the checking-slot of the check-rein by making in it several independent shut slots, whereby the horse may be checked at different heights.

**THE Nevada Manuscript** says: A portion of the material for the elevator to be tested at the North Bloomfield hydraulic mine has arrived here from San Francisco. The elevator will be constructed and put in operation as soon as possible.

**THE Carson Tribune** says: The amount of bullion that comes in from the southern part of the State is very large, and the bricks shipped by the local roads reminds one of olden times, when the Mint was in full blast.

**AN** injunction has been served to restrain the South Yuba Water and Mining Company from selling water to the hydraulic miners dumping into the South Yuba river or its tributaries in the county of Yuba.

**NEARLY** all the silver mills at Butte City, Montana, have shut down, owing to the shortage of milling salt. This in turn is due to the disagreements with the railroads about shipping rates.

**THE** United States geological surveyors now in the field have recorded the altitude at Mt. Pitt, or McLaughlin, Or., as it is generally called, as being 14,000 feet above the level of the sea.

**THE** new leaching works of Mr. Wenban at Cortez district are operating very successfully. During the last month 59 bars were shipped, weighing about 100 pounds each and over 500 fine.

**THE** relocators of the Lightning Liz claim, near Dayton, are said to have uncovered a four-foot vein of gold-bearing quartz assaying \$100 per ton.

**THE** Marysville foundry has suspended operations temporarily. It is stated that the help have not been paid for two months.

**THE** closing down of the Copper Queen mine has occasioned much depression at Bisbee, A. T.

**THE** first bullion from the Nogales (A. T.) smelter was shipped to Pittsburg, Pa.

### Standard Sizes for Iron Axles.

Our readers who use wagon gear—and they will comprise nearly all of our subscribers—will be interested in the following letter by R. G. Sneath, of Jersey Farm, which we copy from the *Carriage Journal*:

The subject of iron or steel axles for wagons and carriages would appear anything but a live subject to write about, and yet they are the innocent cause of sad losses, tedious and expensive delays, untold blasphemy and infinite disgust, to the human family. The manufacture of these highly useful articles, under present methods, is, no doubt, criminal, as their use sadly interferes with the progress of mankind. Webster defines crime as "a public wrong," "that which is condemned," etc., and I will try to show wherein the wrong lies, that it may be condemned.

As near as I can learn, there are, perhaps, 40 different sizes of axles in their greatest diameter—say from  $\frac{1}{2}$  inch up to 5 inches; then there is a variation in length of spindle in each size, of from  $\frac{1}{2}$  to 3 inches, giving, say, 11 sizes in length to each size in diameter, or multiply 11 by 40 and you have 440 sizes simply by one maker. Now, estimating the number of makers in the United States and elsewhere, who make our axles, at 100, we should multiply that number by 440, which makes 44,000 different sizes. I do this because I do not know of any two makers that make alike, in fact hardly two axles by the same maker are alike.

Axle boxes not only vary in fitting axles but differ in thickness and taper; some  $\frac{2}{3}$  inch boxes are  $\frac{5}{8}$  inch thick, while others are  $\frac{3}{4}$  inch. Some nuts are  $\frac{1}{2}$  to  $\frac{3}{4}$  larger on the square end than others of the same sized axle, making from three to four different sized wrenches necessary, at times, for a patched-up wagon. In  $\frac{2}{3}$  inch axles I have noticed a difference of  $\frac{1}{8}$  inch in the taper, between the different makers, and also that it was very difficult replacing lost nuts on account of the various sizes.

In new axles, before the boxes are removed, it is quite essential to mark each arm and box in order to return them to their respective places; otherwise you may have trouble, as they are pretty sure not to be alike, and you may get your hind wheel in front.

Extra boxes to fit closely, in case of repairs, are an accidental thing, and in order to be sure that they are not too small, you are pretty sure to order them a size or two too large. The wobbling, however, of wheels thus fixed is neither pleasant nor profitable. Axles are not marked distinctly enough to prevent the wear and tear, dust and grease, from obliterating the maker's name and marks, and the correct measurement of such axles, when well worn by the farmer or teamster, is a matter of great uncertainty and notorious inaccuracy.

Orders for either axles, boxes or nuts, from such a source, will ordinarily have to be duplicated before a fit is obtained, and should such orders come from the mountains, several hundred miles off, the damage by delay—even of a nut being lost—may run up into hundreds and thousands of dollars, especially when a large body of men and horses are waiting the arrival of some special thing in connection with machinery.

The principal reason of serious delays and loss in this respect is that nearly all orders on this coast must come to this city, as there is no stock to speak of carried elsewhere. The next is the difficulty of filling the order after its arrival here. Most of the wagons and carriages in use here are of all conceivable sizes and patterns and come from the Eastern States, and, notwithstanding the great wealth of the wholesale dealers in these articles in this city they are not equal to the task of furnishing 44,000 different kinds of axles and make the business pay. Consequently, the old axles and boxes must be thrown away and new ones take their place, or the orders sent East to be filled, perhaps, by the maker, while the stock of axles here is dwindling down under this process to a point that is not even respectable, and in smaller towns hardly any stock is kept.

Iron boxes that vary in thickness cause a short life to wheels, for, in replacing in one case, the hub must be cut to admit the larger box, and in the other the hub must be filled with something to enable the smaller box to stay in place, and in neither case can the farmer or teamster place the box centrally and securely.

If the boxes were made uniform in inside and outside diameter, and of a standard pattern, upon the principle of a gun and its cartridge, exactly alike of a given size, then any person could replace a broken box without loss of time or money.

If axles, boxes, nuts and wheels were interchangeable like our government's arms, or the mowers, reapers and farming implements of the present day, then a few extras would accommodate a whole neighborhood of farmers. The village blacksmith and the country store could then be persuaded to keep extras, for there would be a profit in it.

In a business I have myself, I employ about 30 wagons. They were picked up from various sources and no two are alike. I soon found myself in trouble in the matter of repairs, and I then adopted one make of axles and one size for each department. Also one size of wheel and one width of tread (five feet to outside of tires), and one width for shafts and poles where attached to the wagons with springs, as well as one size and make of springs. I keep a few springs and axles and extra boxes and wheels,

perhaps a dozen of the latter, so that in painting and tire-setting the wheels can be shifted. And now I have no delay from breaks, as about all my wagons are now up to standard sizes, through repairing.

It may be of general interest to say that I receive about 12,000 pounds of milk daily from Jersey Farm Dairy, San Bruno, Cal., on thoroughbred wagons carrying 6000 pounds at a load, going five miles an hour, on axles  $2\frac{1}{2} \times 2\frac{1}{2} \times 12$ , making 60 miles daily or 22,000 miles annually, or 150,000 made in the last seven years by two wagons that are alternated for repairs. One of the wagons had axles  $2\frac{1}{2} \times 2\frac{1}{2} \times 11\frac{1}{2}$  which were always grinding and heating, and needed oil continuously, notwithstanding any set or gather we gave it, and it was only used while repairing the other. But upon changing the axles to the size and taper of the other, it gave entire satisfaction. I estimate the life or duty of such an axle, loaded and cared for properly, at 50,000 miles; and of the tires, 1x3, at 5400 miles. My experience favors a  $\frac{3}{8}$ -inch taper to 12 inches in length, and in axles  $1\frac{1}{2}$  to  $2\frac{1}{2}$  inches diameter; the length should be about five times the larger diameter, as giving the greatest strength and durability.

I think it would be safe to say that on this coast, with two millions of people, there are at least 1000 stores and places where at least 10 sets of axles with boxes and nuts would be kept, if the business was simplified by the adoption of a few standard sizes, that were uniform and interchangeable. These axles being worth say \$10 per set, would make the stock of 10,000 axles, at \$10, \$100,000. The wholesale stores in this city, and other large towns in the interior, would perhaps carry 5000 axles more, which would figure \$50,000, or \$150,000 worth, in all would be carried by the trade over and above what is now carried.

Now, the whole United States having 30 times the population we have, would, if the same ratio is preserved, carry four million five hundred thousand dollars worth in excess of present stock, or with extra boxes and nuts from five to six millions.

I can remember the time when, to get a one-half inch or three-eighth inch nut for a carriage bolt, it was necessary to visit the blacksmith, as no two nuts or bolts were alike, and he would perhaps have to recut the bolt or make a new one, as his screw cutter was unlike anybody's else. But now I venture to say that there is not a farm, store or shop on the coast where a three-eighth or one-half inch bolt and nut could not be obtained, either new or second-hand, and so it should be with nuts for ordinary iron axles for farmers; they should be obtainable anywhere.

The enormous growth in the trade of those articles that are manufactured cheaply, on a grand scale, because of their uniformity, interchangeability and general use, can be noted in carriage and machine bolts, guns, pistols and cartridges, clocks and watches, mowers, reapers, sewing machines and many other things.

It is only a few years since every planing mill in this city had a different gauge for flooring, and if a builder obtained flooring from two yards his floors would be spoiled, as the tongue and grooves would not match. Now all are alike.

It seems remarkable to me that in this modern age so large a number of respectable people should be engaged in a calling wherein the public are damaged to the extent of millions of dollars annually through unnecessary delays, while they themselves are ruining their own market for their goods to the extent of millions also, and without having an apparent knowledge of the fact.

There should be a combined effort on the part of all manufacturers, dealers and users to concentrate this business to a few standard sizes that can be agreed upon by the dealers and makers; and hardwood dealers are particularly interested in the matter, as the enormous variety of wooden hubs they are now constrained to keep makes their business unprofitable.

Wagon and carriage makers by adopting standard sizes for wheels, especially for those most largely in use, and keeping extra wheels on hand for sale, would, no doubt, find a large demand for wheels that are finished in iron and paint, for emergencies, as thousands are broken every month and people have not time to wait for weeks for the paint to dry on a repaired wheel.

And why not agree at the same time for width of tread and tires and between standards of bolsters, size of king-bolts, distance from doubletree to axles, length of tongues, etc., so that the bodies, racks, breaks, bolsters, tongues, etc., can be interchangeable.

These reflections come from 40 years of actual and active experience, and the figures I have given, as the probable result of a change, I candidly believe to be not far out of the way. I have mentioned this matter to several gentlemen, who have dealt largely in wagon materials for many years, who have universally coincided with me in the belief that this whole business has become intolerable and should be remedied immediately; and that if half a dozen axle manufacturers, or less, should take hold of the matter promptly and advertise thoroughly that their work was interchangeable there would be no difficulty in selling all they could make, rapidly, at better prices even than now.

**THE** Lynx Creek mill, Arizona, is making a very successful run, and the Del Pasco is grinding out plenty of gold.

## Passing Events.

In San Francisco we have had a sort of holiday week incident to the Annual Encampment of the Grand Army of the Republic. The city is filled with strangers from all parts of the country.

The closing down of the famous Copper Queen mine, in Arizona, is the result of the long-prevailing low price of copper. This mine is the most important in Arizona, and its production has been so large as to exert a decided influence on the copper market.

The low price of silver is causing a number of low-grade ore silver mines to close down, there being no margin of profit with the present heavy discount.

The success of the pneumatic-tube mining experiment on the Feather river, referred to elsewhere, will doubtless lead to the system being adopted in other places for river mining.

New Mexico is having an excitement over the gold discoveries in the Territory. Numbers of men are flocking to the new district.

The shut-down of the Crown Point shaft threw nearly 250 miners out of employment in that and the Belcher mines. The time required to line up the settled hoist-engine at the head of the incline cannot be accurately estimated. It will not occupy over 30 days at the furthest.

## Lead Mining in Nevada.

For two or three years the Richmond Consolidated Mining Co. (an English corporation), Eureka, Nevada, have held a large quantity of lead on hand, refusing to sell on account of low prices; but in June of last year the price began to go up, and the company finally sold 7538 tons at prices ranging from £14 12s to £19 per ton of 2000 pounds. They have still some 6000 tons of lead on hand. The expenses at the mine have been considerably reduced. For instance, the mining, which was \$11.75 last year, is only \$9.03 this year. That is a reduction on every ton of ore of \$2½. Those items include the cost of the dead work, which has been considerably larger than in previous years. The smelting expenses are very much the same as last year, viz.: \$10.07, as against \$10.39—practically the same amount. The directors paid dividends this year of £35,667. They smelted in the general furnace 7117 tons of Richmond ore, and 5552 tons of purchased ore; and 342 tons of low-grade Richmond, and 1940 tons of purchased ore by the No. 4 furnace, working in connection with the refinery. Thirteen thousand one hundred and sixty-three ounces of gold, 444,368 ounces of silver and 2045 tons of lead have been produced in the year. Lead having gradually improved in price since June, 1885, 7538 tons have been sold during the financial year at prices varying from 3.65 to 4.75 cents per pound; the stock on hand, consisting of 6151 tons, has been valued in the accounts at 4.70 cents per pound; and in consequence of this increase in the price of lead, the directors are enabled to restore the reserve fund to the amount at which it stood in 1884, namely, £75,000.

The cash received during the year for gold, silver and lead, according to the directors' report, is £221,367, and the estimated value of bullion in transit (after allowing for all unpaid refining and marketing expenses) is £153,472—together £374,839—from which, deducting the value of the bullion on hand Feb. 28, 1885 (£154,107), and £71,478 paid for expenses, leaves £149,253 as the net value of the bullion produced in the year. The cost of mining, dead work, smelting, purchasing ore, renewals and repairs, and all other working and general expenses at Eureka, was £101,928. The profit for the year on mining, smelting and refining is £47,380.

The ore has been of better grade than last year, the average assay being \$66.83, as against \$57.32, and the yield per ton of ore has been this year \$59.35, as against \$51.77, an increase of \$7.58 per ton. The expenses of mining have been reduced from \$11.75 to \$9.03 per ton of ore, notwithstanding that a larger amount has been expended in dead work. The smelting expenses have also been slightly reduced, namely from \$10.39 to \$10.07 per ton. The amount paid for purchased ore has been £40,838 for 7493 tons, as compared with £48,181 for 8940 tons last year. The furnaces were shut down in March and April, 1885, in consequence of the great difficulty in getting sufficient supplies of ore and fuel on account of the snow and bad roads. Smelting commenced on May 1, with the usual two furnaces, the general furnace smelting ore and the refinery furnace smelting drosses, accretions from the slag dump and low-grade ore.

The exploratory work done in the mine during the year consists of 584 feet of drifts as against 279 feet last year. The cost of this dead work is included in the mining expenses. No large bodies of ore have been discovered, but the small bodies found on the 300 and 400 levels have further developed, and ore of good quality has been extracted from them. Prospecting is now being carried on in several places. Explorations have been carried on in the Williamsburg and Hoosac mines on a small scale. In consideration of the payment of \$85,000, all suits against the Richmond Company have been dismissed, and the liens on the Albion mines, buildings and works transferred to the Richmond Company, to enable the company to resume possession of the mines and other property. While the rise in the price of lead has enabled the directors to restore the reserve fund to the amount it stood at in 1884, namely, £75,000, they are enabled to state that the profit on the year's working is due principally to the intelligent manner in which the mines have been worked, and the thanks of the shareholders are due to Mr. Probert not only for this but for the successful way in which he

has, by his own inventions, been able to treat the speiss, whereby the profits of the company have been considerably increased; and the directors hope, now that the company is free from litigation, that he will be able to devote himself to the carrying out of still further improvements.

## The State Mining Bureau.

William Irelan, State Mineralogist, having in great part recovered from the severe injuries received a few weeks since near Sonora, has again left on a tour through the central mining counties of the State. While absent on this trip he will visit the more important mines and mining localities in Nevada and Sierra counties, including also, perhaps, some portions of Placer and Plumas counties. Meantime, Dr. Degroot has been deputized to look after the group of counties occupying the northwestern angle of the State, where he is now engaged in the discharge of his duties.

Our newly appointed State Mineralogist seems to be going about his work in a sensible and practical way, visiting and inspecting the mines himself in the more central and accessible districts, and procuring such inspection to be made by competent parties in regions more remote. It is his purpose, as we learn, that the data to be embodied in his forthcoming report shall be obtained, as far as possible, from original sources of information. With such purpose carried out, it may be expected this report will contain more new facts and fresh matter than usually find place in documents of this kind. That this report will not be voluminous may be inferred from the comparatively little time left for its preparation.

The effecting of further economies in mining, more especially in the metallurgy of the business, will be with Mr. Irelan a dominating idea. Much attention, will, therefore, be paid by him and his assistants to the processes employed in the treatment of sulphurets and the reduction of base ores, these having become matters vital to the success of many mining enterprises in California. The plan of procuring from mines being worked or in course of development samples of ore and of the inclosing wall-rock will be largely adopted, these samples, properly labeled, being preserved in the Bureau as well for general reference as for the guidance of the prospector and miner. Under the new management the mineral collection has been subjected to a careful revision, whereby some redistribution of its contents became necessary. It was found that the prior classification of the specimens had, in several instances, been based on the localities of their occurrence or other artificial conditions, rather than on their common properties and characteristics. In all these cases a more natural arrangement has been adopted, and one more in conformity with the requirements of science.

In his endeavors to systematize and otherwise improve the Mining Bureau the State Mineralogist finds his efforts ably seconded by the board of trustees, all of whom manifest a lively interest in the welfare of the institution, several of them devoting much of their time to the consideration of ways and means calculated to increase its popularity and add to its usefulness. Mr. J. Z. Davis brings to the aid of the State Mineralogist the fruits of a long and valuable experience in mining and kindred matters, while in Counselor Heydenfeldt that official enjoys the benefits attendant on a trained and cultured mind and sound legal guidance. Messrs. Durden and Snyder, filling respectively the positions of secretary and assistant mineralogist, have wisely been retained by Mr. Irelan, who could have found no men better fitted to fill these places.

So well officered and conducted, if now the Legislature will make suitable provision for the sustenance of the Mining Bureau, there is abundant reason to believe that it will in a very short time more than repay all it may have cost, and ultimately prove one of the most useful and creditable institutions ever founded by the people of this State.

FURTHER discoveries of gold are being reported in the northern part of Western Australia. Several men are said to have made their way into Sydney from the supposed gold fields. They report the new field as likely to be the largest in Australia. A rush of diggers has already arrived at Sydney en route to the new fields.

## Victorian Gold Mines.

In some parts of Victoria, N. S. W., they are having somewhat the experience we are here; that is, they are now beginning to rework quartz mines, which, under former conditions prevailing there, could not be operated at a profit. In Castlemaine district, 28 years ago, there was a population of 15,000, but there are now barely a third of that number. The drifts were mostly hard, being simply banks of decomposed granite 6 feet to 12 feet in depth. The gold in this "cement" was heavy and much water-worn. In those prosperous alluvial days excellent results were also obtained from vein mining, but the claims were generally abandoned at the average water-line, and the resources of the field are evidently far greater than patient, practical working has yet shown them to be. A local registrar of long standing recently produced an interesting synopsis of 12 distinct reefs, once in good repute, which had been heedlessly discarded at an average depth of 183 feet, after a total yield of 85,566 ounces of gold was obtained from 143,641 tons, crushed by primitive mills and crudest methods of treatment. The figures denote the latent power of the "Great Central Gold Field," and in their light alone it is really difficult to conjecture why a region once so productive and full of promise should have lain so long idle, a veritable scene of apathy and desolation. The area now worked is under 40 square miles, and there are 3500 miners.

The placers in that part of Victoria have been very rich, and the veins which produced the gold in such quantities ought to be found somewhere near by, though we have not always been able to in this country. A correspondent of the London Mining Journal gives some interesting facts of the yield of that region: From Forest creek, alone in the zenith of its fame, 14,000 ounces of gold was won monthly from alluvial drifts, and a few details will indicate the value of the veins from which those deposits were originally derived. On one hillside the drift overlying the bedrock, in claims only 64 square feet, yield 3600 ounces on an average. From Hundredweight hill—so named from its heavy yields—Edwards & Co. frequently washed 360 ounces of gold from a tub of soil. At Sailor's flat and the adjacent gully, 4068 ounces were got from claims only 18 feet by 12 feet. On Dinah flat the returns by the simplest means were even more remarkable, one bucketful of earth giving 252 ounces of gold. In Sheephead gully 456 ounces were taken out of one small hole; 1800 grains were found close to reef crossing the line of drift, and elsewhere finds of 50 cents to the tub were not uncommon. The gold yet remaining in the soils of these unsightly abandoned workings is reckoned considerable, if some facile process could be hit upon for its recovery.

## At Rest.

It is with feelings of deep regret that we chronicle the death of Martha D. Ewer, wife of Warren B. Ewer, of the firm of Dewey & Co., who died July 31st, at her residence, 1516 Folsom street, San Francisco, at the age of 51 years. Her death is a sad surprise, for though she had been ailing for some time she was believed to be hopefully convalescent. Mrs. Ewer was a native of Massachusetts, having spent her girlhood days in the neighborhood of Martha's Vineyard. Her companion, an aged mother, son, sister and brother mourn her loss. She was a member of Temescal Grange, Patrons of Husbandry, Ivy Chapter No. 27, Eastern Star, and the Knights and Ladies of Honor. Mrs. Ewer possessed in a remarkable degree the happy faculty of making a sunny home and winning and retaining the confidence of many friends. Her sweet and amiable disposition, cheerful manners, kind and generous impulses, will cause her loss to be deeply felt in the circle in which she moved.

Mrs. Ewer's funeral was held from her late residence on Monday afternoon, August 2d. The services, which were conducted by Rev. N. L. Rowell and Rev. Dr. Pendleton, were very impressive. A fitting tribute was paid to the character and worth of the deceased. The course of mourning friends, the beautiful floral offerings, the earnestness of the sympathy which was tendered to the bereaved ones, were all significant of the fact that home and society had lost one whose life has been precious to all who came within its influence.

## Refining Copper Bullion Produced by Amalgamating Tailings.\*

NUMBER 4.

The tubs were partially filled with the acid needed for a charge, diluted with water to about 20° Beaume and boiled by live steam. The charge was then fed slowly with a small scoop by one man while his partner vigorously stirred the bath with a wooden paddle, both men paddling from time to time. The chief requisite for good work was to keep the material suspended in the solution until it was substantially free from copper. When the bath reached a strength of over 42° Beaume, it was weakened with water so long as any more bullion was to be charged. Sufficient steam was used to keep the solution hot.

The bullion remaining in the dissolving-tub was leached once or twice with dilute acid, and then several times with water, being stirred and boiled each time. The leachings, so long as they contained silver, were drawn into the precipitating tanks. The bullion was put into small lead-lined filtering-tubs, two feet in diameter and three feet high, and washed with hot water until completely free from acid. It was then dried in iron pans and melted in black lead crucibles. The bars produced averaged, in round numbers, about 950 fine in silver and 17 fine in gold, including all cleanup material, which reduced the fineness several points.

### Precipitating Fine Silver.

The precipitating tanks were old settlers from the mill, about 10 feet in diameter and four feet high. They were lined with lead and furnished with a steam-pipe, arranged as for the dissolving-tubs, and were provided with bars of copper laid on the bottom.

The solutions were boiled with steam in these tanks to an extent sufficient to prevent crystallization, and were stirred with wooden paddles occasionally. The silver was precipitated usually in four or five hours; but occasionally trouble was experienced in throwing down the metal completely, and once in a great while the operation was prolonged for 20 or 24 hours before the tests with salt solution showed no chloride precipitate.

The fine silver precipitate was leached with acid and water, and filtered and washed until free from acid in the same manner as the dissolving-tub residues. All wash waters were tested for silver. The washed precipitate was pressed into cakes, dried and melted.

### Crystallizing.

The crystallizers were wooden vats with flaring sides, and were 7 feet long, 3 feet wide at the top and 2½ feet wide at the bottom, and 2 feet high, clear dimensions. They were constructed of 2-inch plank, braced and strongly nailed. The ends were dapped into the sides, which were bolted together with 4 rods. They were lined with 6-pound lead, one piece 7'x7', forming the sides and bottom, while one-half of another sheet, 3½'x5', formed each end. Considerable economy in lead can be effected by cutting the sheets properly. (See Fig.)

The crystallizers, after being filled, were covered with boards and sacking for three or four days, in order that the solution might cool off slowly and gradually, and thus the formation of larger crystals be promoted. Farther than this there was no financial advantage in attempting to obtain fine crystals, for which reason no lead strips were used.

The bluestone, which crystallized on the bottom, sides and ends of the vats, was taken out, washed and dried on shelves for several days, and then broken up and packed in barrels for the market. A crystallizer yielded about 1000 pounds of bluestone of excellent quality—often as much as 1200 pounds. Specimens sent to the Nevada State Agricultural Fair, in 1875, received a silver medal—the first prize. The same specimens were forwarded by the managers of the fair (without the knowledge of the company) the next year to the Centennial Exhibition at Philadelphia, and, as part of an exhibit, received favorable mention.

Too great an excess of acid in the solutions retarded the process of crystallization, increased the proportion of bluestone of too inferior appearance to put on the market, and gave a greater strength of mother liquor remaining after crystallization.

\*Read before the American Institute of Mining Engineers by A. D. Hodges, Jr.

## Idaho Mines.

The "Short Line Mineral Belt"—Placers of Boise Basin—Banner Bonanzas, "Float," Etc.

[For the PRESS by our traveling representative, FRANK W. SMITH.]

The country traversed by the new and popular railway known far and wide as the "Oregon Short Line," from Granger, Wyoming, northwesterly to Huntington, Oregon, has developed during the past few years a mineral belt that bids fair to lay all past discoveries in the shade. The mineral-bearing formations are rich and varied, and the resources of the districts are extensive and easily worked. The "Short Line mineral belt," since the completion of that road and its branches, has come to the front with a showing and at a pace that will soon place Idaho alongside of Colorado and Montana as a producer of precious metals. A review of the vast mineral field in one or a dozen issues of a paper would be impossible, hence we will confine ourselves to a district or two for each letter.

### "Washington County."

This county boasts of vast acres of rich agricultural and stock-grazing lands as well as a large and undeveloped mineral district. The north end of the county has a number of good

### BLUESTONE CRYSTALLIZERS OF THE LYON MINING & MILLING COMPANY.

properties that only lack practical and economical handling to gain for the county a splendid reputation. Weiser is the county seat. Gold, silver and copper mines have been discovered in the upper end of the county. The Seven Devils and a number of other properties sold for big prices, and so far as worked have turned out very satisfactorily. Owing to the county having such a big reputation as a stock and agricultural district, miners have given it the "go-by" to a great extent. The opportunities to invest and those to get property in mines without buying are good, and the prospects for the future are flattering.

### County "Float."

The general formations are: porphyry and lime. There is a small cannon-ball mill on the Daniel Boone in Mineral district.

Concentrated ores can be shipped to Butte, Salt Lake or Denver over the "Short Line" at a profit.

An offer of \$60,000 for the Black Maria, adjoining the Black Hawk, was declined a few weeks ago.

Washington district is 22 miles north of Weiser. The ores are copper and silver, the latter predominating.

Denver and Omaha smelters are bidding for and securing a greater portion of the ore shipments on the Short Line mineral belt.

Miners are wanted to prospect this county and capital to back them. The latter without the former is a detriment rather than a help.

The Black Hawk mine in Washington district is patented; over 400 feet of development has been made. The ores run from \$30 to \$300 per ton.

Farmers are doing most of the prospecting in this county, hence the little said of new finds. In many instances some prospectors have to be told when they do get a good thing.

### Boise City.

"Boise," as the capital of Idaho is familiarly termed by residents of the Territory, is as lovely a little city as one can find in the West. Since its decay as a great stage and freighting center it has become a clean, beautiful and dignified city, and to-day can boast of more broad, shaded streets, handsome and costly residences,

magnificent and stately public buildings (county, Territorial and Government) and fair-dealing, hospitable citizens than any late-day metropolis of a Territory can sum up. The United States has an \$81,000 assay office here that compares well with the capitol building of some States. Gold is bought here for the United States mints, and assays made of ores for miners. H. F. Wild, the assayer now in charge, is a popular and efficient officer, and is spoken of as the "right man in the right place." Idaho's output last year was \$6,000,000. The new high school building, the courthouse, and the new capitol, standing on adjoining blocks, the capitol in the center, all facing the same street, are marvels of modern architectural beauty, while the interior arrangements of the buildings are as near perfect as skill and experience, backed by a liberal expenditure of money, could make them. Boise's shaded avenues, garden orchards, cosy homes midst beds of flowers, with suburban districts of river farms on either side, while the foothills on the east, with mountains in the background and the plains of Kuna on the west, give the surroundings a variety that is not often enjoyed by otherwise more favored localities. The 15 miles stage ride, from Kuna station on the "Oregon Short Line," made in easy riding and comfortably equipped four-horse Concord coaches, is an experience more delightful than tiring, and the accommodations to be had in the way of hotels cannot be excelled in any city of its size on the coast. "Boise" is the "Denver of Idaho," and each year adds to her growing importance as a commercial center, and ere many 12 months pass away the shriek of the

range of mountains on the east and the Payette range on the west. The country lying between these ranges and extending a distance of 20x30 miles abounds in the richest (has been) placer mines on the Pacific Coast—California excepted. Quartz mines of no mean merit have been opened up, and to-day this basin has the best quartz country in the Territory—the best undeveloped and unprotected. During the palmy days of placer mining, and in fact even yet, the miners of the basin have not been weaned from their first love, in but few cases, and in these instances rich finds in quartz have been the rule rather than the exception. During the present season quartz mining has received more attention in this county than ever before. Comparatively speaking, the country is undeveloped except in places. The few quartz mines that have been developed have paid from grass-roots, and some of them have been dividend-producing for years, yet, strange as it may seem, new finds are few and far between until the present season. On second thought, it is not strange that Boise county's quartz mining has been neglected, when one is familiar with the peculiar prejudices of the average placer miner against any method of mining save with the sluice-box and the hydraulic pipe. This class of miners have been located in the basin since '62, and, owing to the national reputation Boise county has enjoyed as a placer-mining district, and the continual excitement and booms of new quartz fields, very few miners experienced in quartz have visited this basin. Now that the water right of the entire basin has been bought up by a few individuals, and they are using nearly if not all of the water to work their own placers, the miner of little or no means must either seek new fields or pastures green, or rustle on the sidehill for quartz. A year hence I dare say a head of water cannot be bought for either prospecting or working outside placers, and at that time the writer will venture to say that the mining news contained in the local papers of the basin will assay high in quartz and show but few colors in places outside of ditch-owners' mines. The field open here to capital interested in and seeking investment in quartz is wide enough to suit the most fastidious, and, in the language of the gospel, "Now is the accepted time." Of course this, like it is used in the pulpit, will be dealt out to the capitalist who is desirous of knowing when is a good time to come, until time shall be no more; but the early bird in this locality is more liable to get the worm cheaper and more of them than he who carries till gold bars and bullion shipments are the order of things daily from the basin, which is very likely soon to be the case.

### Idaho "Undercurrents."

Wages paid in placers are \$4 per day.

The basin gold is worth about \$15 per ounce.

The cleanups of the placers about Idaho City take place about twice during the season and run up into thousands.

Since Wells, Fargo & Co. hauled off their express lines in Idaho the greater bulk of gold shipments are sent by mail.

Noble & Co. own and control some 60 miles of ditches in the basin. Water sells at five cents per inch—when there is any for sale.

The Forest King, nine miles northeast of Idaho City, has a large showing in the way of development, and is equipped with a five-stamp mill (Fraser & Chalmers). The ore runs \$15 to \$40 per ton, and has produced thousands each season for some time past. It is run the year round and is owned by James Moriarty and James Curley.

The "Sub-rosa" group near the Forest King, owned by Hon. M. G. Luney, the popular host of "The Luney House" at Idaho City, has a ten-stamp, wet process mill on the group. The ore runs \$30 to \$40 per ton. This would be a nice property for some company to handle.

The theory that Boise basin has a "false bedrock" and that the richest gravel still lies below this bedrock is a reasonable one, and geologists and scientific mining men are inclined to indorse the theory. Should such prove to be the case the gravel elevator will be just the thing to work every inch of low ground, where otherwise it would be impossible to even prospect.

### Quartzberg Bonanzas.

Quartzberg is a small but live and prosperous camp at the upper or northwest end of the Boise basin, distant about 20 miles from Idaho City. The camp is an old one but by no means worked out. The place boasts of two working properties at present, the Iowa, which has recently started up after a long rest, and the Gold Hill, which has a dividend-paying record regular since September, 1869. The latter is owned by D. E. and Wm. Coughanour of Quartzberg, and Thomas Mootry, of San Francisco. The mine is an old standby and as regular a dividend-dispenser as a tax collector is in his visits.

### Placerville.

This once live and booming camp is now a quiet one, though not a non-producer by any means. A few good placers are worked during the winter season, and good "cleanups" are generally the result. Wages are made by a number of men with rockers.

### Banner District.

This district lies 36 miles nearly due east of Idaho City. It is a silver camp and has a past record as a steady producer. A New York and an Illinois company have the leading mines of

(Continued on page 92.)

## MECHANICAL PROGRESS.

## Inventions Wanted.

People frequently say, says the Cincinnati *Artisan*, that much further progress in the direction of mechanical appliances is unnecessary and impossible; that inventors have almost exhausted the combinations of mechanical movements, and that we have enough helps to make the race perfectly contented, provided every man receives his share of the profits from work done. Before we close the Patent Office, and make it a capital offense for any one to materialize their revelations, we desire to make a few suggestions in regard to improvements which are really needed.

## The Thrashing Machine Dust Nuisance.

We have all noticed the great amount of dust raised by the thrashing machine. The dust is of a very injurious nature, but some appliance is needed to attach to the existing machines to prevent it. The appliance must not be costly, nor complicated, but simple and perfectly efficient. If this problem is solved, the patent can be sold for a good price to almost any manufacturer of thrashers, as it would be a good selling point and prevent an almost unbearable nuisance.

## Connections for Road Steamer Wheels.

A practical apparatus is needed to connect all the wheels of a road steamer, thereby giving higher tractive effects. It must not interfere with the steering gear, but be independent. The parts must be very strong to withstand the shocks incident to rough roads and hard usage in general.

## Improved System of Fire-arms.

An improvement in the present system of small arms, to keep pace with the rapid strides that have been made in the art of war in other departments, is almost a necessity. An improved cartridge, with some very simple, reliable means of firing, would be a great improvement, and the inventor who can discard the common lock mechanism, with its heavy spring, hammer, etc., and produce a perfectly safe and reliable result, will be the possessor of an invention of great value.

## Draft in Locomotives.

Those who are familiar with the principles of the modern locomotive know that the present method of producing a draft of air through the furnace is very imperfect. Back pressure in the cylinders, by contracted exhaust nozzles, has been the cause of a fearful waste of fuel, ever since Stephenson's "Rocket" started on her trial trip. Railroad men are generally too busy to stop and experiment, so the problem will have to be taken up by some one outside their circle. Most experienced railroad men concluded, years ago, that locomotive-builders were contracting the nozzles of the engines too much, and lately inventors have been experimenting with the extensive smoke-box, baffle-plates, screws, etc., and have discovered that by giving the principles of induced currents a more thorough research the parts in the smoke-box and stack could be given a form better suited to a larger area in the nozzle openings, and produce a better draft with much less back pressure in the cylinders, and at the same time relieve to a great degree the emission of sparks. These are real improvements, but cannot be considered perfect.

It has been suggested that a steam chamber, of say greater capacity than both cylinders, be connected to the exhaust passage-ways, the nozzle being attached at the top. This chamber will equalize the pressure of the succession of rapid exhausts, and make a more regular current of steam through the petticoat pipe and stack, thereby producing a regular current of air through the furnace, rather than the "jerky" draft now obtained by the present system. We could supplement the above by the following suggestions from *Mechanics*: Among other inventions wanted, there are calls for macaroni-machinery, separators for mica and graphite, good red lead pencils, comb-grailing machinery, portable power transmitting dynamometer (preferably for belts), type-writers which will work on account books and record books, indelible stamp-canceling ink, a practical car starter, a good railway car ventilator, better horseshoes, radial car axles, independent car-wheels, locomotive head-light, anemometer or instrument for measuring velocity of wind currents, apparatus for measuring the depth of the sea without sounding by line; piano-lid hinge which shall be "flush" on the outside, good fluid India ink for draughtsmen, reciprocation counter for locomotives, solder for aluminium, another good method of working iridium, substitute for coal-tar pitch in making artificial fuel from anthracite coal dust and culm, good metallic railway tie, good independent cut-off for locomotives, flexible book back, method of alloying copper and iron, better facing compositions for iron-founding, good molding material for iron and brass casting, capable of giving mold which can be used over and over again.

**THIN ROLLED IRON.**—As an experiment a piece of iron was recently rolled in the new Falcon mills at Niles, Mich., to ascertain the extreme thinness it was possible to obtain. The result was a sheet about the substance of writing paper—in fact, 150 sheets would be required to constitute one inch of substance.

## The Master Mechanic.

The man who would attain to the position of a master mechanic in any line of mechanical business must acquire something more than mere technical skill, or that knowledge which pertains to the useful or mechanical arts. He should ever cultivate the consciousness that there is always something to be learned in his business, and also very much to be learned outside of it. He should be ever ready to appreciate valuable knowledge from whatever source it can be obtained; carefully study and consider every new development pertaining to his business; and, most important of all, swear unflinching allegiance to duty, to honesty of purpose and faithfulness to principles in the discharge of the important trust devolved upon him. He is most successful for himself who serves his employers best and first. A good foreman or master mechanic is not made of poor material, neither is he the work of a day. His growth in progress is slow, often, perhaps, discouraging, always more or less laborious. He must ever be learning, ever on the alert for some unknown or unforeseen danger, and always awake to those that are known. There is hardly a trade, industry, art or invention with which he should not be more or less familiar, at least so far as to be able to estimate correctly the inherent elements of danger, and its relation, if any at all, to his daily work. The changes made in manufacture are to be noted, and the new dangers involved, if any, studied, counteracted or avoided. A thousand inventions, more or less pregnant with danger, are to be understood, and their hazards or advantages pointed out. In manufactures, every year develops new peril in the efforts made to cheapen cost of production. He should keep himself posted on the various industries of the country; study the financial situation, and watch closely the periods of prosperity and depression, and always bear in mind that there are always dangers to face which the most careful study and the greatest skill cannot fathom, and against which, oftentimes, caution and prudence are powerless, or at least can give but partial protection. In art he should be able to judge correctly of every detail of the workshop, as well as to truly estimate the priceless productions of skill and genius. The best foremen and master mechanics we have in our great workshops to-day are those who have elevated themselves to their trustworthy positions by hard work, close application to study, and who feel themselves fully prepared to assume any responsibilities as they may increase and be placed upon them.—*The Wagon-maker.*

**IRON AND STEEL WIRE ROPE.**—In an article on the manufacture of wire rope at the present time, a recent writer states that although a few years ago such rope was generally made of the best iron—Norway or Sweden preferred—steel has now largely taken the place of iron, especially wherever wire ropes are used for winding over a drum or pulley, or for hoisting, while the best of iron wire will bear a breaking strain of 100,000 pounds to the square inch of section. In this manufacture the very best quality of metal is employed, and the bars are rolled down at a welding heat to wire about one-fourth inch thick; this is then cleaned in warm water acidulated with a little oil of vitriol, and, being coated with a paste of rye flour, is drawn through a succession of holes in a wire plate until it is reduced to the thickness of No. 9 wire, when it is annealed by heating from five to eight hours, and then cleaned and drawn down again until it is of the required degree of fineness. Ropes with 19 wires to the strand are more pliable, and are generally used for hoisting ropes; those with 12 or 7 wires are stiffer, and are preferable for guys, ferries and rigging. Wire ropes are made with six strands, with a center of hemp or wire, the former being more pliable and will wear better over small pulleys and draws.

**THOROUGH WORKMEN.**—There is not a more honorable position in life than that of a good craftsman in a useful occupation. A man with the wisdom of Solomon could not constitute himself a perfect artisan without the practical experience which makes a man such. Journey-men are turned out in multitudes, day by day, who have hardly an idea of the first principles of their trade; and many young men, hardly yet of age, are found bold enough to profess a thorough knowledge of two or more handicrafts, any and all of which they know little or nothing about. Ask employers whence they have their most skilled laborers, and they will tell you they come from those workshops where long apprenticeships served to turn out thorough workmen; where engineering is not learned in a year, shoemaking in a month, or printing in a few days. There are many reasons why this whole subject of mechanical training should be pressed upon our young men who expect to live by mechanical labor. The great enemy of the workingman is the crowd of bad workers who are admitted to his status without the proper experience for which he has paid years of effort.

**SO IT IS SAID.**—Central New York has produced some remarkable men, and has been, and is still, wonderfully prolific in men of inventive genius. The latest is a Utica chap, who has produced out of his fertile brain a farm harness that weighs less than 15 pounds, and does away with whiffletrees, traces and many of the cumbersome straps and buckles. Moreover, it is cheap. What next?

## SCIENTIFIC PROGRESS.

## The Mechanical Equivalent of Light.

The relations existing between mechanical energy and luminosity are for the present unknown; in fact, we know really very little about luminosity and the factors on which it depends, further than that one and the same body becomes the more luminous the higher its temperature. Nevertheless, we can in some cases determine the mechanical work which produces a certain intensity of light by deducting the sensible heat lost by radiation or otherwise from the total amount developed. Generally it is impossible to do so, but the incandescent electric light offers an opportunity for this investigation. Experiments have recently been made at the Technical High School at Hanover, Germany, by Mr. Peukert, in this direction. The radiated heat was determined by a calorimeter filled each time by an exactly weighed quantity of water. The lamp was plunged into it and the water kept agitated. A thermometer divided into tenths of degrees C. indicated the slightest changes. The losses were annulled by placing the calorimeter in an isolating chamber and keeping the surrounding air at about the same temperature as the water. The absorption of light by the liquid was ascertained by photometric measurements in both mediums while making use of Hefner-Alteneck's standard. The current was supplied by a gramme dynamo of Schuckert's make, driven by an Otto gas engine; the difference of potential measured by a Siemens and Halske galvanometer. The current was determined by this instrument in combination with an exactly known resistance. Experiments with three kinds of incandescent lamps gave the following results:

	Difference of potential. Volts.	Intensity of current. Lamps.	Heat absorbed. Calories per hour
Siemens-Halske . . . . .	.98	0.554	36.7
Edison . . . . .	.93.6	0.963	55.26
Swan . . . . .	.76	2.55	124.19

The energy absorbed by an incandescent lamp is converted exclusively into heat and light, so that the portion corresponding to the luminous phenomenon can be ascertained with sufficient approximation by deducting the heat radiated from the total heat equivalent of the energy absorbed. An experiment was made which justifies this way of looking at the subject to some extent. An Edison lamp with a thin copper globe instead of glass was immersed in the calorimeter, when the heat found in the latter differed only by 2 per cent from the calculated total. This would seem to show that rays of light intercepted are converted into heat. If the total energy is converted into calories the results with the three lamps will be as follows:

Lamp.	Total work in calories.	Calories absorbed by radiation of heat.	of light.
Siemens-Halske . . . . .	46.98	35.70	11.28
Edison . . . . .	78.01	55.26	22.75
Swan . . . . .	167.86	124.19	43.67

## Value of the Lens to Man.

Ever since man was capable of observing things around him, he must often have seen that a straight stick thrust obliquely into the water appeared to be bent at its surface. It was a long time before man learned the value of this fact; but at length the lens was discovered. The invention consisted simply in the form given to a piece of glass—in giving to one or both of the surfaces of a disk of glass a curved form. This we know forms a lens, and a lens has become one of the most valuable devices known to man, but it was a long time after its invention before it became of much value.

I alluded to spectacles as a valuable invention. I have never seen any attempt to estimate its value. I do not know that I have ever heard the inquiry made. And yet when we remember that nearly every person above the age of 45, and very many below that age, use glasses, we see that they must enter largely into the sum of our comforts. How many persons would be deprived of the pleasures and benefits of reading and writing during a large portion of their lives but for this simple invention! How many kinds of labor would be performed badly, and with great discomfort, but for these devices! At what disadvantage literary labor would be carried on without them! For how many delicate handicrafts would men and women become unfitted in their later years but for them! At what discomfort and inconvenience would domestic needle-work be performed in their absence! How much trial of the patience is saved by their use! I doubt not our tempers are much better in old age for these helps.

But the value of the invention of the lens is not limited to its use for spectacles. From it has grown up those wonderful modern instruments, the telescope and microscope. Through the former has come a large part of our astronomical knowledge, which has a great commercial value from the security it gives to man in navigating the oceans. It has also a high moral and mental value from the field it opens to the exercise and training of the powers of observation and imagination; from the new conceptions it has given us of the immensity of creation, and of the power which gave it birth. I wonder if any man can rise from a contemplation of the facts, the mysteries and magnitudes of the universe revealed to us by the telescope and spectroscopy, without repeating to himself, with a new sense of its significance, the

question: "What is man that Thou art mindful of him, or the son of man that Thou visitest him?"—Chauncey Smith, in *Popular Science Monthly*.

**OBSCURE HEAT.**—At the late Albany meeting of the National Academy of Sciences, Professor Langley reported on the progress of remarkable researches with the bolometer, by which he has so greatly extended our notions of the invisible spectrum. This time he dealt with the lunar spectrum, and estimated the heat derived from the unilluminated moon. Rosse had estimated the temperature of the moon's surface as from 200° to 500° Fah. By studying the moon at its full, with a rock-salt prism obtained only after repeated failures, and which from its nature had already required repolishing seven times, each time necessitating a new determination of its constants, he had succeeded, on repeated occasions, in securing a spectrum which showed two curves—one according with that previously obtained in the infra-red region beyond the visible portion of the solar spectrum, clearly due to reflection, and another, lying entirely beyond that, as clearly due to the moon itself, and revealing its real temperature. This, as shown by studying the spectrum of frigid masses, is colder than the temperature of melting ice. By comparing the mean of the spectra obtained in summer with that of those obtained in winter, it is evident that a much greater amount of heat is obtained from the moon in winter than in summer. This may simply be due to the greater amount of aqueous vapor in our own atmosphere in the summer as contrasted with the winter clarity. By directing the bolometer to the zenith and the horizon, the temperature of space has also been measured by direct experiment for the first time, and the amazing transparency of our earth's atmosphere to radiation of the earth's heat revealed, for his experiments show that our atmosphere transmits the earth's heat more readily than the sun's.

**GERMANIUM, THE NEW METAL.**—A German technical journal gives an account of a new metallic element discovered by Clemens Winkler. It occurs in argyrodite, a silver ore from the Himmelsfurt mine, near Freyberg. Germanium, symbol Ge, has a great resemblance to antimony, though it is distinguished by certain well-marked reactions. If the sulphide is heated in the absence of air, *e. g.*, in a current of hydrogen, it forms a blackish crystalline sublimate, which at a higher temperature melts to brownish red drops. This sulphide dissolves in ammonium hydrosulphide, and is reprecipitated with a white color by hydrochloric acid, and is again redissolved by ammonia. If arsenic or antimony is present, the color is yellow. If heated in air, or treated with hot nitric acid, the white germanium oxide is formed, which is not volatile at a red heat. The oxide dissolves in potassium hydroxide. If this solution is slightly acidified, it gives a white precipitate on treatment with hydrogen sulphide. The oxide is easily reduced by hydrogen; the sulphide less easily. The metal is gray, volatile at a full red heat, though less readily than antimony. The vapor deposits small crystals resembling those of iodine, which do not melt. In a current of chlorine the metal yields a white chloride, which is more volatile than antimony chloride. The acid solution gives a white precipitate with hydrogen sulphide. Herr Winkler is determining its atomic weight, with a view to determine its place in the periodic arrangement.

**A MERITED RECOGNITION OF A VALUABLE INVENTION.**—The Phelps system of telegraphing to and from a moving train by the utilization of the well-known principle of induction has justly been considered one of the most important inventions of the day. It presents a decided and radical departure in telegraphy, since it was the first practically successful attempt to turn to useful account an electrical phenomenon which had hitherto been not only quite useless but positively a hindrance and an obstacle in the practice of telegraphy and telephony. It is a just tribute to the inventor—the fact that the city of Philadelphia has just awarded to him the John Scott Legacy Premium and Medal for his system of induction telegraphy, on the recommendation of the Franklin Institute, a society which, with increasing years, exhibits increasing zeal in good works.

THERE has been of late so much alarmist talk, says London *Truth*, about the exhaustion of our coal fields that it is good news to learn that an inventor, Mr. R. M. Marchmont, has at last perfected an engine in which the steam is returned to the boiler, and, so to say, used over and over again. The saving in coal thus to be effected is calculated at 80 per cent. Besides saving coal, however, this invention will upset a pet theory of the engineering fraternity, who have always considered this problem as impossible as perpetual motion. It is to be feared that our cotemporary has gone a little in advance of his patronymic.

**WATER JETS AND FLAMES AS CONDUCTORS OF SOUNDS.**—Dr. Chichester A. Bell claims to have discovered that a falling jet of water, or a flame of gas burning in a room, mimics, echoes, and carefully reproduces every word spoken and every sound uttered in a room. Dr. Bell has found that when a couple of friends join in a conversation in the drawing-room of an evening, the gas which burns above their heads repeats every word they say.

## ENGINEERING NOTES.

## Hoisting from Great Depths.

Prof. J. Hrabak, of Austria, in discussing the means that will have to be adopted to raise ore or coal from depths exceeding 1000 meters, points out that that depth was reached in 1883, by the Przibram mines, and that several collieries are rapidly approaching it. He shows, says the *Colliery Guardian*, that the ordinary method with ropes of any form whatever will be practically impossible when the ore has to be raised 1200 meters, without the use of supplementary engines placed lower down the shaft, and that even these would not enable the ore to be raised from depths greatly exceeding 1200 meters. The method that, in principle at least, would enable the ore to be raised from almost any depths is the pneumatic system, which has been in use since 1876 at the Epinac colliery, in the south of France. The results obtained have been very satisfactory; but as the cost of a pneumatic plant would be greatly in excess of a rope one, it is very improbable that it will come into general use as long as it is found practicable to employ ropes. Having this in view, the author proposes a method by which he considers it will be possible to overcome the difficulties attaching to the ordinary rope arrangements. He proposes to increase the width of the shaft for half its depth to such an extent that, besides the two principal winding divisions, two secondary ones could also be arranged. Through the principal divisions, the winding would be effected by ropes that reach to the bottom of the shaft, and they would be worked in such a manner that while half the length of each was wound upon the drum, the other halves would hang down the shaft and counterbalance one another. The ore would be raised by these ropes half the height of the shaft, and would be lifted the remainder of the distance by the secondary ropes. This method of winding would be expensive on account of the enlargement of the shaft, and the necessity for two winding-engines. The expense would, however, be compensated for by the winding power being increased by 50 per cent.

**THE PROJECTED SIBERIAN RAILWAY.**—The completion of the Canadian Pacific Railway has given a fresh incentive to the discussion among Russians of their own long-talked-of line to the Pacific across Siberia to Vladivostok. If Russia has stolen a march over England in railway progress toward Herat, it will be a long time ere the Russian locomotives compete with those of England and America in reaching the shores of the Pacific. The *London Times* says: "The almost chimerical idea of a Russian Pacific Railroad is talked of and written about as an undertaking of early and easy accomplishment. All difficulties are very satisfactorily disposed of except one, which is quite left out of calculation, and that is the source of the 150,000,000 roubles and more that would be required for the enterprise. The addition of the Canadian Pacific Railway to that of the United States naturally makes the Russians feel more keenly than ever the disadvantages of their isolated position on the Amoor and the Pacific Coast." And we may add that in England the feeling is so strong against the enterprise that the judgment is constrained to decide that the same is an impossibility. But Russia will eventually go through Siberia to the Pacific Coast by rail, and find a way for her people and their commerce to either the Indian ocean or the Mediterranean sea—probably both. The interests of commerce and industrial progress demand it.

**THE DISAFFECTED PROVINCES** of the Dominion are moving earnestly in the direction of effecting more intimate commercial relations with the northeastern portion of the United States. Arrangements are said to have been completed for building an International railway across the State of Maine to connect the Canadian Pacific with St. Johns and Halifax. This important line has been proposed for many years, and its completion will greatly shorten the distance between Montreal and western Canada and the maritime provinces.

**FOUR AND A HALF DAYS TO NEW YORK.**—There seems to be a determined effort being made to run an overland train from San Francisco to New York in four and a half days. Those interested in the scheme are exceedingly sanguine of success. Referring to this matter, J. M. Davis of the Iowa line says that the question of doubt is not a factor, as his line has already practically demonstrated the fact that there is increased profit in running a fast train.

**THE USE OF IRON RAILROAD TIES** in this country is not favored by Chief Engineer Brown, of the Pennsylvania Central road, who has been experimenting with them for several years. He says they give perfect satisfaction and are no more difficult to keep in line and surface than wooden ties; but they cost from three to four dollars each, while good white oak ties can be procured for one dollar less.

**CITY RAILWAY OWNED BY THE CITY.**—The 14 miles of street railway in Glasgow are owned by the city, and bring to the treasury a rental of \$76,000 annually. There is no uniform rate of fare, but a penny a mile is charged, with reduced rates morning and evening, when the working people travel.

## USEFUL INFORMATION.

**PILE DRIVING.**—In an article on pile driving, published in the *Railway Review*, Mr. W. L. Clements remarks: Some pilework recently driven shows that piles driven with the steam hammer have greater capacity for sustaining loads than those driven with the drop hammer. The Michigan Central Railroad Company had driven some time ago several hundred piles to protect their bridges from ice. Part was driven by a steam hammer and part by a drop hammer. Some are in clusters and others are standing alone. Those withstanding the lift of the ice are invariably the ones driven by the steam hammer. It would appear that the earth is more violently disturbed by the quivering blow of a long drop and heavy hammer, and the frictional resistance of the pile thereby decreased. The steam hammer, on the other hand, gives a short, rapid tapping to the pile and rather presses it into the ground without intervals of rest, thereby keeping the earth in its natural state. This theory, however, has not been sufficiently substantiated by further experiments, and cannot be stated as a positive fact.

**THE HEALTH-GIVING PROPERTIES OF RAIN** are not appreciated by the general public. Rain is an essential to physical vigor in localities that have any extensive population. Man and his occupations laden the air with countless and unclassified impurities. The generous, kindly rain absorbs them, even as a washer-woman extracts the dirt from soiled clothes. The ammoniacal exhalations, the gases resultant from combustion and decay, are all quietly absorbed by a brisk shower. People talk about a "dry climate," but it is a snare and a delusion. There is nothing in it. A very dry climate will never support a large population, for it would soon become so poisoned that it would be fatal to the human race. A scattering few might inhabit it, but not the multitude.

**VARNISH—FIVE DIFFERENT SORTS.**—Common oil varnish: Resin, 4 lbs.; beeswax,  $\frac{1}{2}$  lb.; boiled oil, 1 gal.; mix with heat, then add spirits turpentine 2 qts. Mastic varnish: Mastic, 1 lb.; white wax, 1 oz.; oil turpentine, 1 gal.; reduce the gums small, then digest it with heat in a close vessel till dissolved. Cabinet-makers' varnish: Pale shellac, 700 lbs.; mastic, 65 lbs.; strongest alcohol, 1000 lbs.; dissolve. Dilute with alcohol. Small quantity, same proportions. Turpentine varnish: Resin, 1 lb.; boiled oil, 1 lb.; melt, then add turpentine 2 lbs.; mix well. Copal varnish (pale): Pale African copal, 1 part; fuse, then add hot pale oil 2 parts. Boil till the mixture is stringy, then cool a little and add spirits turpentine 3 parts.

**SOURING OF MILK IN A THUNDER STORM.**—Some one sent a query to the *Manufacturer and Builder* asking the cause of the souring of milk during or immediately after a thunderstorm. After recognizing the existence of the fact, that journal says that "the most satisfactory explanation that has been offered to account for the phenomenon is that the electricity developed when a thunder-storm is passing causes the formation of ozone in considerable quantity. This is a powerful oxidizing agent, and being absorbed by the milk, converts a portion of the milk-sugar contained as one of its constituents into lactic acid, which in turn acts on the nitrogenous matter (the casein), causing this to coagulate or curdle."

**FOR STAINING BRICKS.**—For staining bricks red, melt one ounce of glue in one gallon of water; add a piece of alum the size of an egg, then one-half pound of Venetian red and one pound of Spanish brown. Try the color on the bricks before using, and change light or dark with the red or brown, using a yellow mineral for buff. For coloring black, heat asphaltum to a fluid state, and moderately heat the surface of the bricks and dip them; or make a hot mixture of linseed oil and asphalt; heat the bricks and dip them. Tar and asphalt are also used for the same purpose. It is important that the bricks be sufficiently hot, and be held in the mixture to absorb the color to the depth of one-sixteenth of an inch.

**LIQUID CARBONIC ACID.**—The recent simplifying of the process for producing carbonic acid is proving of much practical use for industrial purposes, and to meet the demand for the same an enterprising German firm is now building up a large business in its manufacture. It is used for charging beer in the cask, in the manufacture of seltzer waters, and for fire extinguishers. By its expansion the Krupps, of Essen, subject their great castings to the enormous pressure of 1200 atmospheres. Its gas is also expected to prove valuable for inflating balloons to raise sunken ships, heavy weights having been very quickly raised from the sea-bottom by its aid.

**SUNKEN TIMBER.**—When vessels or timber sink to great depths in the ocean the pressure is so great that the water is forced into the pores, and the wood becomes too heavy to rise again. It is this pressure that makes it possible for divers to descend to any great depth.

**THE CARE OF EMERY WHEELS.**—In an interesting paper on "Emery Wheels and Their Uses," by L. Best, in the *American Machinist*, a point is stated which every person who uses

such wheels should remember. It is this: "Have the wheel slip easily on the mandrel; do not force it on in any case, as the expansion of the spindle in case of heating in many cases causes the wheel to break." Mr. Best also says that wheels on automatic planer knife-grinders should run only about 300 revolutions per minute, and that corundum for "sharpening wood-working tools and machine-shop tools is better than emery."

**HOW TO TAME THE WILDEST HORSE.**—Take finely-grated horse castor, oils rhodium and cummin, keep these in separate bottles well corked; put some of the oil of cummin on your hand and approach the horse on the windy side. He will then move toward you; then rub some of the cummin on his nose, give him a little of the castor on anything he likes, and get 8 or 10 drops of the oil rhodium on his tongue; you can then get him to do anything you like. Be kind and attentive to the animal and your control is certain.

**STAINS FOR WOOD—SIX COLORS.**—Red: Brazil wood, 11 parts; alum, 4 parts; water, 85 parts; boil. Blue: Logwood, 7 parts; blue vitriol, 1 part; water, 22 parts; boil. Black: Logwood, 9 parts; sulphate of iron, 1 part; water, 25 parts; boil. Green: Verdigris, 1 part; vinegar, 3 parts; dissolve. Yellow: French berries, 7 parts; water, 10 parts; alum, 1 part; boil. Purple: Logwood, 11 parts; alum, 3 parts; water 29 parts; boil.

**ORANGE STAIN FOR WOOD.**—Yellow or orange stains generally result from the use of nitric acid or turmeric. Thus, 2.1 ounces finely-powdered turmeric are digested for several days in 17.5 ounces 80 per cent alcohol, and then strained through a cloth. This solution is applied to the articles to be stained. Nitric acid diluted with three parts of water is likewise used. A hot concentrated solution of picric acid can likewise be used.

**RAILWAY GAUGES.**—The six-foot gauge is rapidly disappearing from American railways. The five-foot gauge in the South is also being replaced, and the probability is that the standard gauge will soon be a rule to which the narrow gauge will be the only exception.

**A GREAT PUMPING ENGINE.**—The largest pumping engine in the world is used to pump water in Pennsylvania. In one minute it forces 20,000 gallons of water out of a mine to a height of 130 feet.

**GREEN VS. SEASONED OAK.**—It is said that experiments have proved that green oak posts will last longer in the ground than those from the same variety of seasoned timber.

## GOOD HEALTH.

## Recovery From Illness.

I think that only those who have been on long beds of sickness, experiencing weeks of pain and weariness, coming slowly up through convalescence once more, can fully appreciate all that good health means.

In sickness your world is limited to the world of your chamber; your interests to obtaining ease and rest from pain. You are like a babe in your despondency, and a child in your temper and caprice. Strange thoughts come and go through the brain; all the future is dull and lurid, as seen through the morbidness of disease, and between it and you lies the valley of the shadow of death, perhaps. If you escape that valley, and feel life thrilling once more within your veins, how slow the creeping back to the old landmarks once more, and the awakening of the old interests. But one by one they come to you once again, the pulse beats ever stronger until you can cry *jubilante*, I am well.

And there is a compensation of one sort for sickness. The wheels of your machinery have been oiled and jointed afresh, and move with greater ease; the new fibers of flesh and muscle have something of the elasticity of youth about them, and your brain is cleared of many cobwebs. In the hand-to-hand conflict you have had with disease, all minor troubles have lessened or vanished entirely, and the blessings of life so nearly lost are appreciated at their worth.

Hope is in the ascendancy again, and you are thankful, loving, willing, glad to do your part once more in the work of life. All this comes with real healing from disease.—*Herald of Health*.

**CAUSE OF PREMATURE OLD AGE.**—The cause of much of the premature old age and decrepitude and nerve degeneracy and break-down is in the many inventions man has devised whereby he robs himself of timely rest. The morning newspaper, often read through before breakfast; the telephone in his house, to call him at any and all times aside from his repose; the electric light to keep his brain unduly stimulated through the retina; the railroad and the sleeping-coach, which may keep him continuously on the rail (if he chooses so to travel) for many weeks, without rest from the noisome and exhaustive cerebro-spinal concussions of this mode of travel, hasty meals and telegrams and business, and nightmare sleep, all commingled, wither and wreck lives innumerable, which,

under wiser management, might end differently; and the needless noises of the city—the bells and whistles, howling hucksters, noisy street cars, yelling hoodlums, that make night hideous with their howls—hasten the premature ending of useful lives; and when, superadded to all this unphysiological strain, we have the assault of a pestilence that poisons, like cholera, how much exemption can such overwrought organisms expect? How much of resisting immunity can such overstrained and exhausted nerve-force oppose to the invading foe?—*Sanitarian*.

**WHAT IS CATARRH?**—Catarrh is a mucopurulent discharge, caused by the presence and development of the vegetable parasite *amœba* in the internal lining membrane of the nose. This parasite is only developed under favorable circumstances, and these are: Morbid state of the blood as the blighted corpuscle of tubercle, the germ poison of syphilis, mercury, toxæmia, from the retention of the effete matter of the skin, suppressed perspiration, badly-ventilated sleeping apartments, and other poisons that are germinated in the blood. These poisons keep the internal lining membrane of the nose in a constant state of irritation, ever ready for the deposit of the seeds of these germs, which spread up the nostrils and down the fauces or back of the throat, causing ulceration of the throat; up the eustachian tubes, causing deafness; burrowing in the vocal chords, causing hoarseness; usurping the proper structure of the bronchial tubes, ending in pulmonary consumption and death. Many attempts have been made to discover a cure for this distressing disease by the use of inhalants and other ingenious devices; but none of these treatments can do a particle of good until the *amœba* are either destroyed or removed from the mucous tissue.

**HAY FEVER IN CALIFORNIA.**—Dr. Lindley, of the Los Angeles Medical College, has been collecting statistics and reports concerning the disease known as "hay fever" or "hay asthma" in Southern California, and after wide research he enunciates three conclusions: 1. Hay fever never originates in Southern California. 2. All cases of hay fever that have come, seeking relief, to Southern California, have been benefited—almost all have been cured. 3. That a few miles inland, in the foothills, relieves such cases as are not benefited by a residence at the seaside. During Dr. Lindley's researches, Dr. John C. Kerr, of Pasadena, wrote him: "I think you will find it the universal opinion of all physicians that hay fever does not prevail in Southern California." And Dr. J. A. Crane, of Santa Ana, wrote: "Somewhat less than two years since my attention was especially directed to the subject of hay fever in Southern California by a question put to me by the Hon. H. H. Markham, M. C. If I remember rightly, he had been a sufferer from this complaint during a residence East, but had experienced entire immunity from attacks since coming to the Pacific."—*Pasadena Union*.

**A REMEDY FOR HICCUGH.**—Dr. A. G. Gibson calls attention in the *Edinburgh Medical Journal*, April, 1886, to the old Hippocratic aphorism, "Sneezing occurring after hiccough removes the hiccough," and suggests, in cases of hiccough, the production of sneezing by tickling the nostril, and he tells us that he has in this way been very successful in arresting this disagreeable affection. Hiccough, as well as sneezing, is one of the specially modified respiratory movements, and it is quite in accordance with what we know of the transference of nervous action, that the spasmodic contractions of the diaphragm should cease on the induction of the explosive expirations which constitute the act of sneezing. There is one point, however, which deserves special mention. It is not necessary that the stimulus applied to the nose be followed by sneezing. The application of a gentle irritant to the nasal mucous membrane may be quite enough to put a stop to the hiccough, by diverting the nervous energy into other channels, although it may not be of sufficient power to induce sneezing.

**CHANGING THE VOICE.**—As the result of an experimental inquiry, Dr. Sandras, a physician of Paris, claims to be able to change the nature, intensity, pitch and extent of the voice in a surprising degree by the use of different inhalations. A few inspirations of alcoholic vapor impart a decided hoarseness, some vapors weaken the voice, while others strengthen it to such an extent that it acquires new notes, high and low. If the same effects are produced upon people generally, this curious discovery must prove of great practical value to public speakers, singers, and all who use the voice considerably.

**SMOKING AND DRINKING.**—Tobacco blindness is becoming a common affliction. At present there are several persons under treatment for it at one London hospital. It first takes the form of color blindness, the sufferers who have smoked themselves into this condition being quite unable to tell the color of a piece of red cloth held up before them. Sometimes the victim loses his eyesight altogether. Although smoking is to a large extent the cause of the malady, and so gives it its name, heavy drinking is also partly responsible.

**IF A SUMMER SICK-ROOM** has a fire-place, put a candle in it. The upward draft makes an excellent system of ventilation, especially if a window be left open to allow fresh air ingress,

## MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

## CALIFORNIA.

## Amador.

**NEW LONDON.**—Amador Ledger, July 31: Prospecting operations at this promising claim near Plymouth continue with unabated vigor. The shaft is down 400 feet, still in good ore, estimated to go from \$8 to \$15 per ton. The shaft is of a substantial character, made to last, evincing the confidence of the stockholders in the permanence of the mine. It is 8x5 feet in the clear, double compartment, and heavily timbered. No drifting has been attempted so far, but it is probable that at the present level, 400 feet, a tunnel will be run to determine the extent of the ore body. The company will not commence the erection of a mill until the outlook warrants the putting up of a 40-stamp mill. About 23 men are employed about the mine.

**MOORE.**—We are pleased to state that the ore body at the lowest level, 400 feet, was struck last Sunday. It seems to be of good quality, and shows free gold. The ledge was encountered only 20 feet from the shaft, but, before finding it, tunnels several hundred feet in length were run, extending almost clear round the shaft. It seems that the ledge in the lower level has been found on the opposite side of the shaft to where it was struck in the previous level, and this sudden change is what has baffled the prospectors, and led to so much useless labor.

**SOUTH SPRING HILL.**—This mine continues to develop in a manner that stamps it as the coming mine of the county. Heretofore the ore body has been confined to the south side of the shaft, but lately in running a tunnel north they have come across a fine ledge, as rich as any yet met with. The additional 10 stamps to the mill have not been commenced, as far as work on the ground is concerned, although Knight & Co.'s foundry is busy with preparations.

**MISCELLANEOUS.**—Grading for the Kennedy mill was completed last Saturday. The machinery has not commenced to arrive yet. The 10-stamp mill at the Iowa was started up Monday morning. It is calculated to crush two tons to the stamp per day.

## Calaveras.

**ANGELS CAMP.**—Mountain Echo, July 31: Within the past 18 months the tide of prosperity has flowed in this direction, and with the discovery and development of our numerous mines of to-day sprang renewed energy and encouragement in the breasts of its residents. Many of those who had forsaken the town in its hour of decline have returned and re-established homes. Real estate that would scarcely bring \$100 two years ago, now commands from \$500 to \$700. Large steam engines have taken the place of the hand-windlass, and the stamp batteries now perform the work formerly done by the horse and water-power arastras; the Diamond and Burleigh drills have been substituted instead of the antiquated hand-drills; the gold-bearing sulphurets that were formerly considered valueless are now saved systematically and reduced, and the precious metal extracted. The development of our mines continues with a vim never heretofore equaled. Upon lodes which formerly required the work of five or six men, now give employment to from 20 to 60.

## El Dorado.

**RICH GRAVEL.**—Placerville Observer, July 29: James Jeffrey has been made happy the past week by striking immensely rich gravel at the old Green Mountain mine, south of this city. The men who recently had the mine gave it up in disgust, and Mr. Jeffrey went to work with two boys, as much out of curiosity as from a hope of returns. From the start the gravel prospected well, and a few days ago he ran on to a number of nuggets, the largest weighing \$22. Many smaller ones were found, and it is believed the present crushing will yield as well or better than ever before known in this famous old mine.

**SEAM MINES.**—El Dorado Republican, July 27: The seam mines in course of prospecting around Greenwood are looking very well, and there is not much doubt but what this section will soon make a stir in mining circles. T. G. Bilty, who is developing the Garfield mine, has recently run into a blue slate formation, and is very enthusiastic over the outlook. Before leaving the town we called at the stores of Chas. Nagler and F. Ricci, whose well-stocked shelves showed that they were well prepared to furnish the community with all requirements in the way of merchandise.

**KELSEY.**—Owing to the scarcity of water, those engaged in mining the placer claims have been compelled to abandon their work for the present; but judging from the current report, Peter Shepherd is still interested in his American Flat property. Considerable prospecting on seam and quartz ledges is being done in this vicinity, but your correspondent has yet to learn of any one being so fortunate as to have found anything that could equal in riches the palmy days of '49.

## Inyo.

**THE MAXIM.**—Inyo Register, July 29: The Maxim mill near Chrysopolis will start up next week on custom ore. The property has received a thorough overhauling during the last few weeks at the hands of S. D. Thurston.

**TO START UP.**—The improvements which have been and are now being made in the Coldwater-Casey mill are nearly finished, and it is expected that the stamps will be dropped early next week on ore from the Casey mine.

## Mono.

**LUNDY.**—Bodie Miner, July 28: The Gorilla Mining Company are working about 20 men. The mine is looking well, with plenty of ore in sight. The mill runs like clock-work. Erickson, Vance & Co. are having about 25 tons of rich ore, from the Josie Green mine, crushed at G. Ash's arastra.

**THE STANDARD CON.**—Bodie Miner, Aug. 2: Number of men employed in and about the mine, 44. 400 level—South upraise advanced 10 feet; winze, same level, advanced 11 feet. 300 level—West drift north advanced 15 feet; north drift ad-

vanced 18 feet; west drift south retimbering. Ore bodies hold well in quality and quantity. Ore shipped to mill for week, 292 tons. Standard side of Bulwer mill running steadily.

**THE BODIE.**—The south drift from upraise above 400 is extended 25 feet. The north drift, 620 level (Lent shaft), is extended since last report 16 feet in good ore. We are grading for a new mill, jointly with Mono, at the Lent shaft.

**THE MONO.**—The north drift from west crosscut, 700 level, extended 13 feet; there is rich ore in it. The south drift, 700, is extended 23 feet; the east crosscut from south drift, 700, is extended 5 feet. We are grading for a new mill, jointly with the Bodie Con., at the Lent shaft.

## Nevada.

**DEVELOPMENT.**—North San Juan Times, July 31: New mining companies are forming daily in this place, and work of development is being pushed everywhere. Frank Morris and George Powell are opening a ledge on the north side of the Middle Yuba that promises to turn out very rich. We were shown a specimen Tuesday taken from the ledge which carried coarse gold in large quantities. The rock is of the same description as that found in the Boss mine, but the gold appears to be coarser.

**RICH QUARTZ AT BRONCO.**—Truckee Republican, July 27: A fine ledge of gold-bearing ore is said to have been discovered a few days ago, about three miles below Bronco, near the river, on the opposite side from the railroad. The ledge is six feet wide and the rock is said to assay \$75 per ton. The discovery was made by a sheep-herder. A number of locations have been made, and the vicinity is alive with prospectors. This may be a good mining camp some time.

**POWNING MINING CO.**—Grass Valley Union, Aug. 3: The annual meeting of the Powning Gold and Silver Mining Co. was held on Monday evening, at which the following directors were elected to serve for the ensuing year: A. B. Brady, Dennis Meagher, Joseph Gilbert, John Stocks and Charles Nettle. The Board subsequently organized by the election of A. B. Brady as president and superintendent, and Joseph Gilbert secretary and treasurer. A. B. Brady, superintendent, presented a written report at the stockholders' meeting, in which it was stated that a shaft had been sunk on the company's ground, 5x7 feet in the clear, and timbered, to a connection with the shaft sunk from what is known as the Callaghan tunnel, and that shaft cleaned out to the depth of 42 feet, making a total depth of 80 feet. A contract has also been let to sink a shaft near the line of the Coe Company down to the ledge, in consideration of 20 loads of quartz. The shaft is now down 40 feet, with good indications of a ledge. In both shafts the walls are from 3 to 4 feet apart. On account of the quickness of the water, machinery for pumping would be necessary for the further prosecution of work, but owing to the financial condition of the company, it was not deemed advisable to put up such works at present.

## Shasta.

**NOTES.**—Shasta Democrat, July 28: Three mills are running in the Bullychoop district. Barney Conroy is superintending work at the Ballakala mine. The reduction works on the Scheerer mine will be running by the middle of next week. Weil, Conroy & Co. are running a tunnel on the Ballakala mine to tap the ore body between 300 and 400 feet deep. It is thought that by Oct. 1st, or sooner, Jack Conant will be crushing ore from the Uncle Sam mine on Squaw creek. The lower tunnel in the old Fleming mine in Old Diggings district shows up a body of good milling ore 12 feet wide. Johnny Doblin has sold one of his quartz claims on the Clear creek side of Muletown mountain to Shasta parties. It is a fine prospect. A party of Sacramento capitalists were out in Old Diggings district last Sunday, examining some mining property with a view of purchasing. Geo. McDaniels & Co. are developing a fine gold prospect on Olney gulch, about five miles west of Redding. They have sunk about 25 feet on the vein, which is some three feet wide. The ore carries a large percentage of rich sulphurets, besides prospecting well in fine gold. The vein is confined to porphyry and black slate rock. It has all the earmarks of developing into valuable property. The Live Oak gold quartz mine, about four miles north of Shasta on the Iron mountain road, is doubtless one among the many good mining properties in the county. It consists of two full claims which were patented several years ago, a good water ditch that supplies power for the mill, and a good heavy five-stamp mill. Several years ago Mr. Welsh worked 100 tons of ore which netted him a little over \$10 a ton. Knowing that he was not saving all there was in the ore, he shipped a ton of tailings to San Francisco, which worked \$33. This proved conclusively that he was losing more than he saved. Not being a quartz miner, and being engaged with other interests that required all his attention, he shut the mill down, and the property has lain dormant ever since. It is his intention, this fall, to fit up the mill and reopen the mine.

**BULLYCHOOP.**—Anderson Enterprise, July 29: Senator Foster, of Red Bluff, passed up to Bullychoop, in company with George Grayson and Mr. Buckmaster, of San Francisco, last week, and Tuesday evening last the party returned, having in their possession many specimens of gold-bearing and sulphurets rock from that mining district. Mr. Foster has purchased a two-thirds interest in the great Mammoth mine, the mother lode of that mineral belt. This gives the Potts, Foster & Wallace Company control of 3000 feet on this huge deposit of gold-bearing quartz. And their property is in far better shape than it ever was before, and it is quite reasonable to suppose that that great mining interest will, sooner or later, pass into the hands of able quartz operators. Whether Mr. Grayson will take hold of the property hinges on what returns his assays will show. The Mammoth lode, when tapped at sufficient depths, will surely show large deposits of sulphurets ore, carrying a great deal of free gold and, perhaps, considerable silver. But this ledge will have to be struck at about 600 feet in depth, for from about that point up the ledge has given up its free gold to its many stringers, which branch off from the mother vein like branches from a tree. Work in Bullychoop is progressing rapidly. Everybody is busy, mills are running night and day, and the bright "yellow stuff" is being taken out, forwarded to the mint and coined. The Bullychoop Company are taking out exceedingly rich ore at about 25 feet

west of their old original shaft. The Williamson mill is at present running on the Pound Cake rock. Mr. Enright is busy, and crowding his work along as fast as he can. Titus & Co. are also meeting with good success, and are running both mill and mine. Mr. Grant passed down to Red Bluff with Senator Foster, to make a transfer of his interest in the Mammoth, we suppose.

## Trinity.

**QUARTZ SALE.**—Trinity Journal, July 31: During the past week Mr. C. C. Shattuck, of San Francisco, has made a conditional purchase of Wm. Farmer of the mine recently discovered on Hay Fork, and which gives promise of much value. The agreed price is \$7000, a portion being cash down and the balance in installments. Work of development will begin at once.

**SPLENDID PAY.**—Detlef Hansen returned on Thursday from a visit to the Hansen quartz mine, on Know Nothing creek, beyond New River district and on the Salmon side of the mountain. The first cleanup was made from 16 tons of the rock, ground in a 10-foot arastra, which yielded at the average rate of \$80 per ton. This is excellent, the mine promising to be a veritable bonanza, as the ledge is of good size and well defined.

## Tuolumne.

**NEW REDUCTION WORKS.**—Tuolumne Independent, July 31: Prof. B. Shraff has purchased the Experimental Gulch quartz mine, located about 1 1/4 miles north of Columbia, and will put up works—the largest-sized Frisbee mill and Blanding crusher—of capacity to reduce from 40 to 50 tons of ore per day. He has ordered 40,000 feet of lumber of Mr. Bradford for the buildings, and the machinery is now on the way from San Francisco. He has already commenced grading for the buildings. A dozen men will be engaged in putting the property in order, and then some 20 hands will be employed to work the mine. Some 15,000 tons of ore are on the dumps, and 100,000 tons more are above the water level in the mine. The vein runs from 6 to 20 feet in width. The ore, by mill test, yields from \$5 to \$15 per ton. Mr. Shraff intends to have the mine worked in the most systematic manner, and feels assured of success. This mine was located in 1852, and is believed to be the first quartz mine worked in Tuolumne county; and, so far as known, was the first mine supplied with a mill. In a report upon the geology of California, presented to the U. S. Senate in 1856, by Dr. Trask, he says a mill and reduction works were put on this mine in 1854, but the power (water) giving out soon after, operations were suspended for that time. The report says that 1500 tons of rock yielded \$16,150, or over \$14 per ton. Considering the primitive way of working quartz mines in those days, the result showed the ore to be very valuable.

## NEVADA.

## Washoe District.

**CHOLLAR.**—Enterprise, July 31: On the 3200 level the south lateral drift from the Combination shaft station is in 75 feet, following the east side of the ore vein. Thirty feet south of the station a crosscut west has been started, which is now in 30 feet. It is getting into the ore vein itself, the ore met with giving excellent assays. Forty feet north of the station, in the drift going to the deep winze of the Hale and Norcross, another crosscut west has been started, which is now in 30 feet. This crosscut also shows excellent ore indications. This drift, since the completion of the connection with the Hale and Norcross deep winze, has been trimmed out into regular shape, properly timbered, etc., and thoroughly completed to the Hale and Norcross line. The connection was made all right, and the whole level is well provided with good, healthy ventilation.

**SAVAGE.**—On the 600 level the main south lateral drift is being again advanced directly into the valuable ore body found at that point. It is 30 feet or more in width and shows the regular old-time black sulphurets and chloride ore. The best of it assays over \$200 per ton, and it is all being carefully saved for milling. As before mentioned, there is plenty of room there for a good-sized bonanza with millions in it. The face of the drift is 180 feet south from the Gould and Curry south line. Crosscuts Nos. 2 and 3 west from the main lateral drift are in 40 or 50 feet, and the faces of both are in the same good ore vein or deposit found in the face of the main drift, showing that it lies to the west and extends well northward. The crosscut east, together with the lateral drift to the southeast from it, following the clay wall, has been discontinued.

**BEST AND BELCHER.**—The water is easily held at a point about 20 feet below the lowest level, which, as it connects and corresponds with the 2500 level of the C. and C. shaft, is to be hereafter for convenience sake designated as the 2500 level. The air engine and blowers have been placed in position on this level and the air pipes carried through to the point northward, where the heavy stone bulkhead is being constructed. On the 600 level a west crosscut is being run from the main northwest drift at a point 20 feet from the main west drift. It is in 45 feet and in virgin ground, with favorable ore indications.

**HALE AND NORCROSS.**—The connection having been made on the 3200 level with the Combination shaft from the deep winze, work has been concentrated upon trimming and straightening up the drift, putting in drain boxes, etc. A crosscut west will be started in a day or two to intersect and explore the fine ore vein developed in the Combination shaft and Chollar workings on this level. The lateral drift north from the deep winze station for the Savage is looking well, but showing no new feature of interest worthy of special mention.

**CROWN POINT AND BELCHER.**—Shut down at present, all mining work being suspended since Tuesday, in order to make necessary repairs or improvements to the main incline engine on the 1100 level. The settling of the ground had at last got this engine so badly out of line that it was deemed unsafe to proceed with it any longer. It will take probably two weeks yet to get it reset in perfect working order again, but this will be done as speedily as men, money and true engineering capacity can effect the object.

**CON. CALIFORNIA AND VIRGINIA.**—Yielding

about the usual 350 tons per day, assaying, from mill battery samples, not far from \$12 per ton. On the 1400 level two branch drifts have been started from the end of the northwest drift from the C. and C. shaft. One is running in a northerly direction and the other southerly. Both are in favorable material. On the 1600 level the northwest drift is now in about 260 feet. Material, vein porphyry and quartz.

**KENTUCK.**—Forty tons is the regular daily yield of this mine, and not 140, as mistakenly given last week. The Pelton water wheel on the 700 level continues doing most excellent work, supplying the hoisting power in deeper working at merely nominal expense.

**OPHIR.**—On the 1465 level the south drift is being repaired and put in good working order. On the 1300 level the south drift is in 137 feet; material, favorable. Operations on the 300 level are suspended.

**GOULD AND CURRY.**—The only work this week has been in the north drift, 150 feet above the 600 level. This reached a length of 93 feet, with its face in good-looking quartz and other vein matter.

**SIERRA NEVADA.**—On the 520 level north lateral drift No. 2 gained 38 feet, making a total of 388 feet, following along the east clay wall of the ore vein in porphyry with streaks of decomposed quartz.

**POTOSI.**—Owing to delay in procuring the requisite diamonds from below, drill hole No. 6, near the Chollar line, has not been started, but will be in a day or two.

**YELLOW JACKET.**—About 140 tons continues to be the regular daily yield from the 1300 level up. The low-grade ore supply seems inexhaustible in all directions.

**MONTE CRISTO.**—The main drift west on the 150 level from the new shaft is within a few feet of cutting into the ore vein of the mine.

**ALTA.**—The west crosscut on the 700 level is cutting into the old Keystone ledge.

## Bernice District.

**QUIET.**—Reno Gazette, July 30: E. L. Williams, who arrived at Reno from Bernice, Tuesday night, says the camp is comparatively quiet. He says the proprietors of the Golden Crown mine are not doing anything on account of the depreciation of silver. The Hoyt mine is being worked on a limited scale. The ore taken from that mine when sorted for the mill runs about \$150 per ton. The vein is not large, but pays to work. Mr. Hoyt will soon largely increase his working force. The next crushing from the Hoyt mine will be a greater source of profit than any former one. Keeler & Horton are running a tunnel into the Razor Blade claim, which is considered among the best and most prominent claims of the district. James Ironside is at work on his claim known as the Moonshine. From the present indications that claim will develop into a good mine.

## Cottonwood District.

**TO WORK THE NICKEL ORE.**—Eureka Sentinel, Aug. 1: R. H. Parker, treasurer of Churchill county, is building a hotel at Cottonwood. About the first of July the English company that purchased the cobalt and nickel mines made another payment of \$6000 to George Lovelock, who located the several claims. The company is preparing to work these mines on a large scale, and the prospects are that Cottonwood will soon be a lively camp.

## Esmeralda District.

**LOOKING UP.**—Walker Lake Bulletin, July 29: Aurora is once more looking up, times are improving, and miners and business men are becoming more hopeful. It is reported that there is considerable improvement in the ore of the Humboldt mine owned by the Esmeralda Consolidated Co., and its mill is constantly running. The company has also started work on another of its mines. Mr. Colcord, the superintendent, will remove his family from Bodie to this place, and will occupy the two-story brick building, known as the Sanchez house. Work is being vigorously prosecuted on the Antelope. They are still taking good ore from the Lord Byron. Tanagerman is now hauling ore to the Miner's mill from the '85, formerly the Prospectus.

## Eureka District.

**ORE SHIPMENTS.**—Eureka Sentinel, July 27: During the past week ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Richmond works—Silver Lick mine, 20 tons; Bullwhacker, 11; White Pine, 6; Empire, 7; Colorado, 7; Oregonian, 2; Geddes and Bertrand, 6; Hoosac, 4. To the Eureka Con. works—Dunderberg mine, 38 tons; Alexander, 32; Summit, 10; Black Prince, 2; Reveille, 1; Ernst, 1/4.

**SPEISS FURNACE.**—Eureka Sentinel, July 27: The Sentinel learns that Mr. B. S. Bernard, of the Ruby-Dunderberg Mining Co., will shortly establish a furnace in Eureka for the working of speiss, refractory and low-grade ores, which, if it meets his anticipations, will undoubtedly create a revolution in ore smelting on the Pacific Coast. Inasmuch as letters patent have not yet been granted in America on the furnace and process, we are unable to give particulars of the invention, which originated with a Frenchman, and on which letters patent have been granted in Australia, Spain, England, France and other countries. Mr. Bernard says the furnace and process are in successful operation in Europe, and that \$10 ore can be worked here and made to pay. Another good feature is the cost of the invention. He says a furnace with a daily working capacity of 30 tons can be established in Eureka for \$2500. The fuel used is charcoal and coke, and by condensation of the heat generated the economy is surprising.

## Osceola District.

**LEASED.**—White Pine News, July 27: From Hon. Robert Briggs, just in from Osceola, we learn that Jack Gilmer, who owns half the Eagle mining and milling property, has leased the other half from ex-Senator Spencer. He has now a force of men at work on both mine and mill, and expected to start the mill the latter part of this week.

## Ophir District.

**BULLION.**—Belmont Courier, July 29: The output of bullion continues steady from the Chicago Mining and Reduction Company's Works at Ophir.

## Park Canyon District.

**TOO REBELLIOUS.**—Belmont Courier, July 29:

Work has been suspended in the mine and mill of Park Canyon. The ore proved of too rebellious a character for profitable leaching.

#### Secret Canyon District.

**NOTES.**—Eureka *Sentinel*, July 27: The Scorpion mine is yielding ore, some of which is very rich with horn silver. Large deposits of oxide of antimony and silver are said to exist in Woodside canyon. Sam Delmew has just made a shipment of ore to the furnaces at Eureka from Woodside canyon. The boys leasing the Irish Ambassador are said to be taking out some very rich ore since their last shipment. Morris Joseph is working alone at present in the Water Jacket mine, putting it in shape for fall and winter work. It is looking very well. John Steel has just made a shipment of rich ore from Cave canyon to the furnaces at Eureka. The amount was small, but prospects for larger quantities are good. The Geddes Company has given several parties the privilege of prospecting some of their claims for what they can find, requiring no tribute, but reserving the privilege of taking the pitches and putting the adventurers on day's pay. Messrs. Pope and Hanlon have returned from White Pine and will prospect the Slackton ground, where very rich ore is known to exist. The old hands of the camp are confident that there are valuable ore deposits in that ground. Ben. C. Levy, of Eureka, is backing Charley Turner, who is running a tunnel in Cave canyon to tap a well-known vein of rich ore at the bottom of an incline, which has been filled up with waste rock. The scheme is said to be a good one. J. Berryman has taken a lease of the Munroe mine. This property in former years yielded some very rich ore, and assays from samples that were taken from several places a few days ago gave results from a few dollars up to several hundreds. Barney McRory and Tom Gilligan are driving a tunnel to tap the ore veins in their property. They have abundant water in the tunnel for all mining, and, if necessary, milling purposes. They will soon commence laying a track to facilitate their work. Capt. J. M. Foley has just completed a new connection from the surface with his tunnel, which had caved for a hundred feet near the mouth. At the junction some timbering will be done. This tunnel is intended to tap several ore veins in a larger tract of mining ground. Hon. Thomas Wren and a party of friends were out from Eureka lately viewing this property. Charley Ruden and the Berrymans, who have been so fortunate lately in the Iron Clad mine, Page canyon, are still at work and continue to do well. They will shortly resume work in the tunnel in order to tap the old works, in which remain immense piles of waste rock, which they intend sorting over. Out of this they expect to realize very good results. The clearing out of the waste rock will also give them a chance to prospect the old workings that paid handsomely in former years.

#### Sprucemont District.

**PANNING OUT.**—Cor. *Elko Free Press*, July 26: Our population at present is small, but a bright prospect for an increase at an early date. The mines are panning out well. The ore is being shipped to Wells by teams, thence to Salt Lake City for reduction, owing to the smelter being switched off on a side track.

#### Ward District.

**FINE BULLION.**—White Pine *News*, July 27: Supt. Culver, of the Martin White, at Ward, shipped this week bullion 925 fine, while dispensing with the roasting process. This is the best showing ever made there. Even with roasters, which are a heavy expense, Martin White bullion never before went over 715 fine.

#### Wild Rose District.

**PARADISE VALLEY.**—*Silver State*, July 27: Milling ore, 194 tons, 500 pounds; shipping ore, 23 tons, 1030 pounds. Total, 217 tons, 1540 pounds. Ore delivered to the mill, 217 tons, 1540 pounds. Number of tons of ore milled, 145. Average assay value, per ton, 62.12 oz. silver, 0.39 oz. gold. Bullion produced, from 31,035 lbs. concentrates, \$10,862.66 par value, 282 sacks of ore, estimated value \$3214.50. Shipped to Boston & Colorado S. Co., Argo, Colorado, concentrates and ore valued at \$14,077.16. Mill work—Three Huntington centrifugal roller mills and six Triumph concentrators. Number of men on payroll, 126, of whom 46 are miners; on dead-work, 31; ore extraction, 15; ore sorters, sack sewers and rock breakers, 12.

#### ARIZONA.

**MOHAVE CO.**—*Miner*, July 27: J. Quaid and Rees Jones have leased a portion of the Christie mine, near Honkle's wells, and are getting out some good ore. Tom Christie will make a shipment of ore in a day or two from his bonanza. Harley Fay had several tons of ore from the Black and Tan mine worked at the Kingman sampling works last week. Wm. Miller had a carload of ore worked at Kingman on Wednesday, from the Hackberry South mine. Beecher & Co. have taken the contract to haul all the ore from the Signal mine to the mill, a distance of nine miles. Johnny Burt makes his last shipment from the Rainbow mine under his present lease to-day. Hereafter the mine will be worked by Messrs. Sherman and Patridge, the owners, in conjunction with Mr. Burt. Charley Richardson made a small shipment of ore from his mine near Chloride yesterday. Johnny Seidel shipped a couple of tons of high-grade ore from the Juno mine last night.

**DUNCAN.**—Cor. *Clifton Clarion*, July 20: Our neighboring town of Carlisle is picking up rapidly and enjoys a mild sort of a boom. A stamp mill has been erected at East Camp, and the ground near the company's works in town is being graded preparatory to the erection of a new 20-stamp mill.

**COPPER.**—Notwithstanding the drop in the price of copper, individuals here and there are doing quite a good deal toward the development of copper properties. Among the new claims which promise well is the Fairbanks, discovered by Messrs. Hill & Campbell and recently sold to Mr. Church. This mine is near the Queen and adjoins the Ray of the Arizona Copper Company. The vein is from 12 to 14 feet in width, and yields a rich ore of green carbonates running from 20 to 40 per cent in copper. A shaft 58 feet has been sunk to a considerable depth and about 200 tons of ore are now on the dump. Messrs. Hill & Campbell have secured the contract from Mr. Church to do extensive develop-

ment work upon this claim. Adjacent to this are the claims Gen. Miles, Panama and Gen. West, owned by these gentlemen, and all promising well.

**PLACERS.**—Mr. W. R. Muir has shown us some fine specimens of coarse gold which he washed out on Chase creek. Gold occurs in considerable quantities in the cement and gravel along the Frisco and in its tributary gulches, and we have no doubt but that some system will yet be devised to work these placers on an extensive and profitable scale.

**MILLS.**—Prescott *Courier*, July 30: The Catocin mine is being worked 70 feet below the surface. A level and stope are being run. The pay streak is from one to three feet thick; the ore thereof is all rich. Near by, Geo. Wickler and Mr. Ferguson are getting rich ore in their mines. The Basin mill, near Bradshaw mountain, has had to suspend, on account of scarcity of water. A gentleman just from there tells us that a great many lots of ore remain to be crushed. The Del Pasco people have added a self-feeder to their little mill, and are running 12 out of every 24 hours on gold rock which pays in the neighborhood of \$50 per month. Capt. Brann has been working rock from a small ledge near the Bully Bueno, which, he states, paid very well. The Peck mill will soon commence crushing ore from an old dump pile. Those who ought to know say the mine will not be free of water for some time. A dry-washing machine, made by Ed. I. Johnson, is in successful operation between Prescott and Skull valley. It is claimed that it saves very fine gold. Three men in 5½ days secured \$93, all fine gold. Those who have seen it work say it is a great improvement upon all other dry washers.

**NO REASON FOR DESPONDENCY.**—*Silver Belt*, July 27: People of Globe have no reason to be despondent over the outlook for copper mining here. The Old Dominion Company is abundantly able to continue operations, even with the present low market for copper. Their mine, the Old Globe, never looked better than now. The ore bodies are large and the ore of very high grade, and it is confidently expected that after September 1st work will be pushed more energetically, with an increased force of men. The consignment of 100 tons of coke to J. Liberman & Co., for the Old Dominion Company, in addition to nine carloads recently received at Wilcox, is significant of the company's intentions.

#### COLORADO.

**LEADVILLE.**—As Denver and all Colorado owe much of their growth and present prosperity to Leadville, there is not a citizen of the city or State who does not rejoice in the renewed mining activity in the carbonate camp. It is not too much to say that Leadville is a busier city to-day than it was five years ago. There is not the slightest doubt that Leadville's new boom rests upon a sure foundation. There are three or four mines that can ship a hundred tons of ore a day for several years. This is a strong statement, but it is made upon trustworthy authority. There are other mines that are shipping a great deal of ore, and which promise to have a heavy output for some years to come. Properties that for a year or more were neglected have been reopened, and strikes have already been made in some of them. It is only natural that a great deal of development work should follow the good feeling which exists in Leadville. The output for this year will be very large.

#### IDAHO.

**ABOUT THE SMELTERS.**—Ketchum *Keystone*, July 24: The company is making daily shipments of bullion. Improvements are constantly being made at the Philadelphia smelter. Workmen are now engaged in putting in new roasters, which, when completed, will enable the company to treat all ores mined in the country. Ores from the smoky region containing base metals can be worked advantageously. The company mines, the North Star, Ten Brooke, West Fork and Ervin, are coming to the front and are making daily ore shipments to the smelters. A rich vein of carbonate ore has been struck in the West Fork which shows every indication of widening out as the depth increases.

**CONCENTRATING.**—Coeur d'Alene *Sun*, July 27: The owners of the Bunker Hill and Sullivan mines are considering a proposition from the concentrating company to increase their contract, so as to warrant the erection of additional works of large capacity. Eight men were discharged a day or two ago because the concentrator was not able to dispose of the ore as fast as the force employed could get it out. The present works concentrate an average of fully 60 tons per day. In Buckskin gulch, boxes are being set to-day on claim No. 2. There will be a cleanup next week, and judging from the appearance of the ground and the bedrock, it will be a good one.

**FLINT.**—Idaho *Avalanche*, July 31: This old mining district has been resuscitated, and under the management of Mr. R. B. Stanton is again showing signs of life. There are about 65 hands at work in the camp, 50 of whom are employed in and about the mines and in grading for the plant and building necessary houses. The place is probably one of the liveliest in the Territory, and as work progresses, no doubt more men will be employed, until Flint will remind one of old times. All the old settlers in this country have the utmost confidence that the camp has an abundance of rich ore, and that all that is needed is a man who understands his business, as we are informed Mr. Stanton does, to make it not only one of the liveliest but one of the best dividend-paying camps on the coast.

**CHARLES DICKENS SOLD.**—*Challis Messenger*, July 27: The Charles Dickens mine was sold last Wednesday noon, in front of the Challis house, at sheriff's sale, to satisfy the judgment of W. S. McCormick and John E. Dooly and various liens, and brought the sum of \$52,000, or about two-fifths of the indebtedness of the estate. The one-third of the mine that was located, held without change and owned by William A. Norton at the time of his death, and against which W. S. McCormick's stood, was sold separately and brought \$24,000, and the other two-thirds brought \$28,000. This amount—\$52,000—was a few hundred dollars short of enough to pay the mortgages above mentioned and three preferred liens and interest and costs. The property was purchased by Jas. W. Hamilton, of Challis, for Robert C. Chambers, of Salt Lake City.

#### MONTANA.

**BEAVERHEAD.**—Cor. *Inter-Mountain*, July 27: The usual steady influx and shipment of ore continue. On account of the many sources from which it is received, the platforms are kept piled full awaiting the arrival of sufficient of the respective kinds to make up a shipment. The first shipment of bullion from the Ball smelter was made last Monday. It consisted of 480 bars weighing 70 pounds each. The smelter was closed down during the week on account of needed repairs and shortage of charcoal, but will start up the first of the coming week. Encouraging reports come from all the mines being developed; especially is this so of the Kent, Bismark and New Departure, which are said to have struck ore bodies larger and richer than any heretofore encountered. Mr. James McGrail, formerly of Cornwall, and Chas. Alstrom, assayer, arrived Friday morning from the East, as experts to visit the tin mines. Some of the specimens shown them here caused considerable enthusiasm. Mr. J. T. Connor visited your city during the past week to obtain a few more men to put the finishing touches upon the mill of the Dillon Mining Company. Mr. Julian Smith, J. B. Scheicky, and two others accompanied him upon his return. The mill is nearly complete. Mr. M. Hogerty is setting the boiler in position. The Bannack Con. is still idle, and Bannack necessarily is despondent. I am requested to suppress notice of a large sale of mining property which, though considered sure, it is thought best not to publish until part of the money is actually paid.

#### NEW MEXICO.

**SOCORRO NOTES.**—*Bullion*, July 25: We are informed that the Ambrosia mine, in the Magdalena district, has been sold this week to Mr. Foley, of Leadville, for \$20,000. T. J. Hudson, one of the most reliable prospectors in this section, is prospecting in the Water Canyon gold belt for a wealthy Virginia syndicate. H. A. Robinson, of Kelly, is preparing to run in a 500-foot tunnel on one of his most important properties, situated in the vicinity of the Ambrosia. The Bullion, Ida, Napoleon III and Nellie will all be actively explored next week. All of the claims are recent locations, made adjoining or in the immediate vicinity of the Ruby mine. John McCalla, the old-time Pueblo prospector, made three locations last week in Hell and Ellis canyons. It is his opinion that he has the same character of rock as is found in the Ruby. Socorro is wild with excitement over the recent rich gold strikes made near that place. They are said to exceed in richness anything ever before discovered in the Southwest. Guy Cox and W. M. Glasson have returned from Garcia canyon, where they have been prospecting. They express themselves well pleased with the gold outlook there and in the vicinity. T. Dorsey, C. T. Brown and Ed Henson will commence work Monday on the Maud, a northeast extension of the Ruby. One thousand dollars will be spent immediately in opening up this promising quartz claim. The Chloride mine, in Pueblo district, has a three-foot vein with two-foot pay streak. This week we were shown assays made at the U. S. mint and by Prof. Dickinson from this ore which run as follows: 69 ounces, 53 20-100 ounces and 53 2-100 ounces silver.

**THE GOLD BELT.**—Socorro *Bullion*, July 25: In corroboration of the *Bullion's* view of the existence of gold in place on the east slope of the Magdalenas, we offer to our readers the opinion of Manager J. B. McGee of the Graphic M. & S. Co., who for two years was head smelter of the Richmond Con. Mining Company of London at Eureka, Nev., and for three years manager of the same company. Coming from such a source, his opinion carries weight. Manager McGee has, from personal observation, come to the conclusion that an important gold belt lies on the east slope of the Magdalenas, commencing at Water Canyon or further south, and extending north until it crosses the A., T. & S. F. railroad, where it crops out in the Eozoe mine and other claims in the vicinity.

**GOLD STRIKE.**—Silver City *Enterprise*, July 29: One ton of ore shipped from the new gold strike near Socorro by the Graphic Smelting Company returned \$7215 in gold and \$150 in silver. There are other prospects in the immediate vicinity of the new strike which are said to be very rich. The new strike has caused great excitement and many prospectors are flocking to the scene. As near as can be learned at this distance the new strike is not extensive. It is simply a very rich pocket of gold ore, and does not justify the great rush that is being made to that point. When in St. Louis, the preliminary arrangements were entered into by Capt. Cooney and capitalists there, looking toward the erection of a smelting plant at Cooney camp. The plan is the same as has been proposed by the captain and prominent metallurgists with whom he has been in consultation regarding the matter. It embraces all the features of the original scheme, including a copper matte smelting furnace and refinery. If carried out, the project is one that will materially benefit the whole camp. Funds for the purpose are now being subscribed in St. Louis. The new mill at Telegraph was compelled to close down last week owing to the low stage of the water in the Gila river, which is said to be lower at the present time than it has been in the history of the Telegraph camp. Five stamps of the mill were run for 11 days previous to the closing down, and everything is said to work very satisfactorily, but some slight changes will be made before the mill again resumes operations. A mining deal was closed in this city on Wednesday which is of the greatest importance to the Gold Hill camp, which will, in the near future, doubtless become one of the leading producers of Grant county. The Standard and the California mines, the former of which has been a steady and profitable producer from grass roots, was purchased by George H. Utter, of Santa Fe, from Fred Rogers, John McLane and Napoleon Heart for \$15,000 spot cash. It is Mr. Utter's intention to immediately commence development work on an extensive scale, and also to erect a new plant with a capacity of 25 tons per day, using the Lucop pulverizer. He will also put in pans and settlers, which will enable him to treat all of the ores of the camp. The mill will be running in four months. Jesse Davis has been engaged as superintendent of the property.

#### OREGON.

**QUARTZ AND PLACER.**—Jacksonville *Times*, July 31: Operations at the Sterling mine are suspended for the season. Work is progressing satisfactorily on the tunnel C. C. Beekman is having run to tap his ledges on Jackson creek. Piatt & Shanks, who have been mining on Louse creek, Josephine county, secured some fine specimens of gold. The Wagner Creek Mining Co. is still crushing ore from the Pilgrim ledge, which promises well. A cleanup will soon be made. A number of huge blocks and a considerable quantity of lumber are now being hauled to Shively gulch for Baumle, Klippel & Co.'s quartz mill. Dan Fisher and Wm. Stuart are engaged in winddamming Rogue river. B. W. Huston has sold his interest in the mines at Foot's creek to his partner, Chas. Anderson, for \$600. He will probably mine in the Willow Springs district next season. McKenzie & Co. have let the contract for getting 100 tons out of the New El Dorado ledge on Jackson creek, and delivering it at the new mill on Shively gulch to Klippel & Co. at \$1.50 a ton. Blacklock, Owings & Co., who purchased several acres on Jackson creek of Judge Duncan a few months ago, picked a nugget of gold worth \$80 out of the cement they are crushing, as also several smaller pieces. A Gold Hill correspondent of the *Oregonian* says: F. M. Johnson, of San Francisco, agent for the Wiswell quartz mill, has purchased D. F. Fisher's ditch around Gold Hill. He contemplates putting up one of the mills, with a view of working Gov. Chadwick's mine. Ray & O'Donald, who discovered the rich pocket of quartz on Gold Hill which raised such an excitement last winter, are crushing quartz with an arastra and doing well. How much they extracted from the pocket is still a mystery, though the sum probably was not nearly so large as rumored. The California company, which purchased mining property in Josephine county some time since, has let a contract for digging four miles of ditch below Kerbyville to Fawn, the Chinese tye of Waldo, which will be five feet wide on top. They have a number of white men engaged in constructing waterways, and will eventually build a ditch from Sucker creek to the Illinois river, a distance of about 16 miles.

#### UTAH.

**SILVER REEF.**—Southern Utah *Times*, July 29: J. Hutchinson made a small shipment to the River mill from Toledo. Hessel-Maxwell leachers are in operation, and doing satisfactory work under a new process. It is expected that another shipment of sulphides will be made this month. Bailey, Nesbit & Co. leachers now have the Wall rolls crushing ore, beginning last Friday week. These rolls do better work than any other patent yet offered, and their capacity ranges from 5 to 6 tons an hour. The mill has had a thorough overhauling, and is ready for a long run. Uneasiness is felt by mine-owners, on account of the steady decline of silver and the momentous question as to how much more it will drop. A much greater reduction will close our mining industry. The Stormont's Buckeye mine furnished the River mill 34 tons of ore daily. The Thompson also furnished a few tons. The Buckeye stopes on the 700 are without change, and the ore bodies are about the same extent, with but little variation in value. The California is in every respect without change; the stopes on 3, 4, 5 and 6 are looking nicely and are producing ore. At the New Shaft, sinking continues, and at the bottom a break has been encountered which shut off the ore body. A crosscut is now being run to tap the ledge on the other side of the break. The crosscut below the Black stope is in 40 feet, exposing about six feet of good ore.

**ORE AND BULLION SHIPMENTS.**—For the week ended yesterday the Mackintosh sampler received 374,190 pounds of Ontario ore, and 102,720 pounds of Daly, and 89,130 pounds of Sanson ore. During the week the Crescent shipped 173,561 pounds of concentrates and about 236,000 pounds of first-class ore. The Ontario bullion shipment for the week aggregated 36 bars, containing 19,431 fine ounces of silver. Another shipment of Ontario bullion will be made (to-morrow) Sunday. The output of Daly bullion from the Marsac mill for the week ended July 24th was six bars, containing 6562 fine ounces of silver. On July 28th a shipment of seven bars of 7647 ounces, and on July 31st a shipment of six bars containing 6640 fine ounces of silver was made.

#### WASHINGTON.

**THE RICKEY HILL MINES.**—*Stephens Reporter*, July 27: About 15 miles west from Colville, and one mile from the Columbia river, are the famous Rickey Hill mines, that are attracting the attention of Montana capitalists. The particular group of which we speak are the Boston, Cleveland and St. John, although there are more properties that have promising outlooks on the hill. They belong to Mr. John Rickey, Marcus Oppenheimer, and the heirs of Capt. Pinkston, the late commander of the steamer *Kootenai*, running between the Little Dalles and Farewell. These properties have been leased by Mr. M. Courtwright, representing Messrs. Hauser & Holter, two of Montana's heaviest capitalists. About \$1500 of work has been done, and a number of men are now at work developing the prospects. There is a 30-foot tunnel in slate, run in to tap the vein. Very rich mineral is found, as croppings showing silver chlorides, recently assayed, going \$150 per ton, and ore working up in free amalgamation 85 per cent silver. The surface croppings run 3000 feet in length, and 15 feet wide, showing a vein that would attract the attention of all mining men. Good ore can be traced all along the vein. The west wall is granite, the east chlorite, with veins running three points east of north, and the same west of south. Some of this ore runs up into the thousands. An extension of time was asked on the bond, and has been granted, and it is thought \$10,000 will be spent to make the proper developments and open the mine. It is proposed to tap the vein with a 150-foot tunnel. Undoubtedly it will show this to be a property that will rival the best yet found in the Territory. A beautiful stream runs right past it, and a grand forest surrounds it. Standing on the mine, one can see the beautiful scenery of the Grand Rapids of the Columbia, and hear the roar of the rushing waters. The experts sent out here by all parties have reported favorably on this section, and at no distant day this will rival the best camps of Montana.

# DAMAGED BY FIRE!

## Engines, Boilers, Wood and Iron Working Machinery, Belting, Etc.

### FOR SALE CHEAP!

The fire which destroyed our building, Nos. 25 to 31 Main Street, on the 20th of June, will have no effect on our business.

We have already secured one of the stores in the magnificent Donahue Block, Nos. 34 and 36 Fremont Street, near Market, the finest in the city.

We have removed our Machine Shop to Nos. 225 and 227 Beale Street, and are now in full blast.

Our Oil Warehouse is located at 519 Front Street.

Our Oregon Branch is still at 91 and 93 Front Street, Portland.

Constant arrivals of new stock will enable us to supply our customers with everything of the latest and best description.

In addition, we shall have all of our old stock of Machinery, much of which had just come in, removed from the burnt building to our new store, where we shall be able to offer it at **EXTREMELY LOW PRICES.**

When the fire occurred, we had, fortunately, finished shipping the mammoth mills for La Trinidad and Silver Queen Mines, of Mexico, and the 20-Stamp Mill for the Buchanan Mine, of Tuolumne.

Notwithstanding our fire, the Pacific Lumber Company, of Humboldt, awarded us the contract for their new mill over all competitors, preferring to wait till our New Shop was ready rather than get their Machinery elsewhere, though they are in a great hurry. We consider their action conclusive evidence of the superiority of our Machinery, as they are determined to have the finest mill on the Coast.

Our New Concentric Set Works and Headblocks, and the Sinker, Davis & Co. Band Log Mill, which we recently furnished the Humboldt Lumber Company, of Humboldt, are pronounced by them superior to any ever seen in Humboldt.

We are now at work on nine Headblocks for Pope & Talbot Mills on the Sound.

From the above facts, it would appear that we stand fire pretty well, and if our patrons will kindly continue to favor us with their valuable business, we will do our best to excel our former efforts.

## Idaho Mines.

(Continued from page 85.)

the camp. The Banner group of mines, owned by the Elmira Silver Mining Company of New York, consists of seven claims. The Banner, Crown Point and Wolverine are the best properties, so far as developed, of the company, the two former especially, they having produced considerable money.

## The Banner.

This claim is 1500x600; course of vein, east and west; dip, nearly perpendicular. The general formation of the country is granite and porphyry; here the vein matter lies on or against a granite foot-wall and is capped by a porphyry hanging wall; the ore-body being a blue, brickle quartz, varying in width from 6 to 18 inches, carrying sulphide, antimony, chloride, ruby, horn and native silver; the latter occurring in chimneys and with a regularity that is surprising. The ore from the levels of this mine has run on an average of \$107 per ton; this, too, for a season's run. Development has been pushed, apparently, with a view of taking out money rather than a systematic opening which this property deserves. A two-compartment shaft has been put down on the ledge to a depth of 400 feet. Levels have been run at 200, 300 and 400 feet, as follows:

## Two Hundred Level.

Eastward from the shaft a tunnel, nearly 200 feet on the ledge, with one or more floors stoped out. Westward on this level, over 500 feet in tunnel and stopes have been excavated, showing ore still in all the headers.

## Three Hundred Level.

East about 175 feet on a good 8 to 10 inch vein. West 300 feet on average size vein, portion of which was not as high a grade. This level has been stoped up to within about 20 feet of the 200 level. The ore taken out of the floors of this level runs well and showed the property averaged all the way down. An 8000-gallon sump on this level drains it, and a No. 6 Knowles vertical plunger pump raises the water to the surface for use in the boilers.

(To be continued.)

## Siphon Action in Discharge Pipes.

EDITORS PRESS:—In a recent issue of *Wood and Iron*, I find a reprint of my recent letter to you relating to siphon action in hydraulic pipes, with some comments by the editor, that call for notice on my part. I am represented as finding fault with Mr. Van Loben Sels' pumping plant—promulgating theories, writing diatribes and so on. I am at some loss, as the readers of *Wood and Iron* must be, to find the connection between my letter and the comments.

In the first place, I was in no position to judge of the expediency of arranging Mr. Van Loben Sels' plant with siphon pipes, and plainly intimate as much in my letter, believing, at the time, that Mr. Van Loben Sels and the makers of the machinery could best judge of that matter. The main point of my letter was to disclaim authorship of the statement that this arrangement of pumps was being adopted to the exclusion of non-siphoning pipes in Europe. This matter is not mentioned in the editor's remarks, and the purpose seems to be, as before said, to put me in the position of contending with Mr. Van Loben Sels and the Tool Co. The expediency of providing for siphon action in pump, discharge or other pipes is hardly a matter for discussion, and certainly not one to connect with the merits of a particular pumping plant.

A siphon discharge pipe properly cleared has nothing to do with a pump's performance one way or the other, as the editor of an engineering journal should know.

In respect to theories I am at a still more loss to know what is referred to, and must conclude that the remark relating to negative pressure equal to the difference in water level of the discharge must be the "theory" referred to.

If so it is good theory—is, moreover, obvious fact. If there is other means for maintaining siphon action in such pipes I am not aware of it.

It may in California, as elsewhere, be expedient or even necessary to employ siphon pipes. It is a problem belonging to the particular circumstances in each case, and, as I said before, is as old as iron pipes, and, as further claimed, is avoided by hydraulic engineers whenever avoidable. This is the point. It is not determinable by particular facts or cases, but a proposition relating to general hydraulic practice. If there is anything new in the matter I am not aware of it, and will gracefully concede the mistake of the position.

Sausalito, August 5, 1886.

## Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

## Mining Share Market.

The share market is in a very depressed condition, and prices fluctuate very slightly. Crosscutting west has commenced on the 2200 level of the Chollar, and Norcross will follow suit directly. These crosscuts have not yet got into the main ore vein, but will do so shortly. The rich ore body recently developed on the 600 level of the Savage mine shows better as further developed. The body is about 30 feet in width, the great proportion of which is ore of the rich, old, early-times Comstock character, kindly and fertile in quality, liberal in quantity, and assaying over \$200 per ton. The low-grade ore bonanzas at both the north and the south ends of the lode continue to hold out well, but a temporary set-back is experienced in the Crown Point and Belcher mines, caused by having to shut down for the purpose of lining and straightening up the heavy hoisting engine at the head of the incline on the 1100 level of the Crown Point shaft. This throws about 250 miners out of employment for a couple of weeks, after which work will be prosecuted to better advantage than ever.

## Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Moulton, July 27, \$15,904; Alice, 30, \$22,886; Silver Bow, 31, \$10,440; Plutus, 30, \$6000; Freeland (for June), \$28,366; Argus, 24, \$6400; Martin White, 24, \$5400; Pyrenees, 27, \$5000; Germania, 27, \$6013; Alice, 28, \$11,835; Germania, 29, \$7644; Hanauer, 30, \$3130; Stormont, 30, \$3305; Queen of the Hills, 30, \$1690; Germania, 30, \$3912; Hanauer, 31, \$3255; Germania, 31, \$3709; Pascoe, 27, \$2111. The Salt Lake banks shipped last week \$127,372 in bullion. From Salt Lake the last week's metal and ore shipment was as follows: 36 cars bullion, 868,347 lbs.; 26 cars ore, 701,770 lbs.; 4 cars copper ore, 115,050 lbs.; 4 cars sulphur, 140,000 lbs.

## New York Metal Market.

Telegraphic advices dated August 4th give the following New York prices:

BORAX—6 1/2% @ 7 1/2%  
BAR SILVER—91 1/4 per oz.  
COPPER—LAKE—\$10.00  
IRON—No. 1, \$17 @ \$18.00; No. 2, \$15 @ \$16.00.  
LEAD—\$4.85 @ 4.95.  
QUICKSILVER—43 @ 43 1/2 c # lb.

The following is the latest by mail from the "New York Metal Exchange Market Report":

COPPER—Quiet but steady; Lake offered at 10.00c. Transferable Notices (Lake) offered at 10.05; Transferable Notices (Chili Bars) offered at 13.95.

LEAD—Nominal at 4.80 @ 5.00c. Transferable Notices (Domestic) issued at 4.90.

TIN—Weaker, closing at \$21.50 @ \$21.75. Transferable Notices issued at \$21.85c.

SILVER—New York, 93 1/4 per oz. London, 42 1/4 d. MAKER'S PRICES—At tidewater. 100 ton lots of listed irons (when brand is specified) range nominally about as follows: Lehigh, Grade No. 1, \$18 @ \$18.50; No. 2, \$17.00 @ \$17.50; Grey Forge, \$15.00 @ \$16.00. Hudson River, Grade No. 1, \$18 @ \$18.50; No. 2, \$17.00 @ \$17.50; Grey Forge \$15.00 @ \$16.00. Southern, Grade No. 1, \$18.00 @ \$18.50; No. 2, \$17 @ \$17.50; Grey Forge \$15 @ \$16.

Prices generally ruling for metals not regularly dealt in on call at the N. Y. Exchange, covering extremes of buyers' and sellers' views. All prompt delivery.—Australian Tin, \$21.70 @ \$21.85; Billiton Tin, \$22.25 @ \$22.50; Banca Tin, \$22.40 @ \$22.80; Baltimore Copper, \$9.25 @ \$9.75; Orford Copper, \$9.25 @ \$9.75; P. S. C. Copper, \$9.25 @ \$9.75; Foreign Lead, \$4.80 @ \$4.90; Foreign Spelter, \$4.80 @ \$4.85.

## Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

## List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey &amp; Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in DEWEY &amp; Co.'s Patent Office Library, 252 Market St., S. F.

FOR WEEK ENDING JULY 27, 1886.

346,350.—HORSESHOE—J. E. Bingham, Walla Walla, W. T.  
346,351.—HORSESHOE—J. E. Bingham, Walla Walla, W. T.  
346,150.—WATER-PROOF COMPOSITION FOR FELT SHOES, ETC.—Feldmann & Dunbar, Portland, Or.  
346,287.—PIE-PLATE LIFTER—G. H. Hollidge, Tacoma, W. T.  
346,105.—BURGLAR ALARM.—J. E. Hunt, S. F.  
346,304.—WATER FILTER—McLean & Cumming, S. F.  
346,212.—PRESSURE-REGULATING VALVE—P. F. Morey, Portland, Or.  
346,226.—HORSE COLLAR—R. M. Sears, S. F.  
346,333.—BRAKE BEAM CONNECTION—Walsh & Smith, Taylorsville, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

COPPER.—Exports of copper from the port of New York in June aggregated 5,840,986 pounds. From January 1st to July 1st the exports of copper ores from all ports of the United States aggregated 16,672 tons, valued at \$1,339,784; of ingot bars, etc., 7,488,341 pounds, valued at \$762,412; of sheet copper, 14,275 sheets, valued at \$2396; other manufactures, \$38,857; total copper exports for half year, \$2,143,440. Last year, in same time, the value of exports was \$4,358,685.

## Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

JARED C. HOAG—California.  
G. W. INGALLS—Arizona.  
E. L. RICHARDS—San Diego Co.  
R. G. HUSTON—Idaho and Montana.  
GEO. McDOWELL—San Luis Obispo and Santa Clara Co's  
FRANK W. SMITH—Idaho and Montana.

MEADOW LAKE.—The *Truckee Republican* advises people to go a little slow on the new Meadow Lake boom. It says: "The works being put up there are merely experimental, and may prove as flat a failure as all which have heretofore been tried. It is well enough to have confidence, but it won't do to bet much money on Meadow Lake."

THE oldest reliable optical establishment, C. Muller, the leading optician, 135 Montgomery street.

## TWENTY-FIRST

## Mechanics' Institute Fair,

SAN FRANCISCO, 1886,

Opens August 24th, Closes September 25th,

—IN THEIR—

IMMENSE PAVILION ON LARKIN ST.,

WITH A GRAND DISPLAY OF

NATURAL AND MANUFACTURED PRODUCTS OF THE PACIFIC COAST, including a magnificent collection of Oil and Water Color Paintings, Art Work, and Photography; MACHINERY in operation; a SPECIAL FLORAL EXHIBIT each week; the finest display of FRUITS, GRAINS, and VEGETABLES ever before presented to the people, and a Grand Instrumental Concert day and evening.

The San Francisco and North Pacific Railroad Company and the South Pacific Coast Railroad Company, and the steamers under the management of Messrs. Goodall, Perkins & Co. will transport perishable articles consigned to the Mechanics' Institute Exhibition free of charge, and other articles at half rates.

LIBERAL PREMIUMS of Gold, Silver and Bronze Medals, Diplomas and Cash, will be awarded. Members of the Institute entitled to Season Tickets at half rates.

PRICES OF ADMISSION—Double Season Ticket, \$5; Single Season Ticket, \$3; Adult's Single Admission, 50 Cents; Children's Single Admission, 25 Cents.

Full information given or sent on application to the Assistant Secretary, 31 Post St.

W. P. STOUT, Sec'y. P. B. CORNWALL, Pres.  
J. H. GILMORE, Sup't. J. H. CULVER, Asst. Sec'y.

## The EXPLORERS' and ASSAYERS' COMPANION.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

## LUBRICATION.

Our readers can procure of CHARLES J. WOODBURY Manufacturer of Oils, 123 California St., San Francisco, a fine Lard Engine Oil, unsurpassed by any other Oil for general use, and which will flow through any feeder at all temperatures. Also, Cylinder Oils, Refined Cylinder Tallow, Lubric Compound, Farm, Machine, and strictly pure Lard Oil. The Woodbury Oils are in use on the Central, Southern, and Northern Pacific Railways, and on nearly every Railroad and Steamship line on the coast.

## American Exchange Hotel,

SANSOME STREET.  
Opposite Wells, Fargo & Co.'s Express, one door from Bank of California, SAN FRANCISCO.

This Hotel is in the very center of the business portion of the city. The traveling public will find this to be the most convenient as well as the most comfortable and respectable Family Hotel in the city.

Board and Room, \$1.00, \$1.25 and \$1.50  
PER DAY, ACCORDING TO ROOM.

Hot and Cold Baths Free. None but most obliging white labor employed. Free Coach to and from the Hotel.

MONTGOMERY BROS., Proprietors.

NATIONAL ASSURANCE CO.,  
OF IRELAND.

ATLAS ASSURANCE COMPY.,  
OF LONDON.

BOYLSTON INSURANCE COMPANY,  
OF BOSTON, MASS.

H. M. NEWHALL & CO.,  
GENERAL AGENTS,  
309 & 311 Sansome St., San Francisco, Cal.

Send for Circular.

Dewey & Co.'s Scientific Press  
Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

DEWEY & CO., Patent Agents.

ADAMANTINE  
Shoes, Dies and Crusher Plates

We manufacture the above Adamantine Shoes, Dies and Crusher Plates. They are in use on the hardest quartz in the United States and South and Central America, and have been ADAMANTINE. for the last ten years; we warrant them to out-wear three (3) sets made of any other metal, and many report that they last from 4 to 8 times longer than any other make. They never break AT THE SHANK, and the wear is so light that little or no foreign matter gets mixed with the crushed ore.

Also CHROME CAST STEEL for Mining and General Use, of the finest quality.  
For further particulars, address

## CHROME STEEL WORKS.

H. D. MORRIS, Agent, 22 Fremont St., San Francisco.  
When ordering, a rough sketch, with full dimensions, is all that is necessary.

CALIFORNIA  
ARTIFICIAL STONE PAVING CO.

(SCHILLINGER'S PATENT.)

—FOR—  
SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE  
DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

OFFICE, 404 MONTGOMERY STREET, SAN FRANCISCO.

EGBERT JUDSON, President. ALBERT H. REICHLING, Secretary. G. GOODMAN, Manager.

## THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as  
The Safest and Strongest High Explosives in the Market.  
**GIANT POWDER or DYNAMITE,**  
Of Different Strengths as Required.  
NOBEL'S EXPLOSIVE GELATINE, which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.

## JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blast ing Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

## BANDMANN, NIELSEN &amp; CO.,

CAPS and FUSE for Sale. GENERAL AGENTS. SAN FRANCISCO, CAL.

THE GUTTA PERCHA AND RUBBER MANUFACTURING CO.

### A Good Opportunity for a Ma- chinist.

A variety of good Tools, Patterns, etc., with business  
for sale cheap, by a party retiring from business. A  
splendid opportunity for an enterprising mechanic.

Address A. B. O., care of this paper.

## HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold  
in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co.  
(Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting  
that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works,  
Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded  
to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quanti-  
ties to suit purchasers.

BALFOUR, GUTHRIE & CO.,

316 California St., San Francisco.

**JENKINS PATENT VALVES.****Gate, Globe, Angle, Check and Safety.**

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." # \$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,  
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.**  
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco. As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement. The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them. Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for. N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

## WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

## BAKER'S MINING HORSE POWER.

Possessing ALL THE REQUIREMENTS of a FIRST-CLASS HOIST, and affording means for the CONTINUOUS OPERATION of a BLOWER, WITHOUT interfering with the HOISTING APPARATUS. It is made ENTIRELY OF IRON, no piece WEIGHS OVER 300 POUNDS. At the ORDINARY SPEED of a horse, a 700-pound BUCKET OF ORE may be raised 75 feet per minute. The HOISTING-DRUM is under the COMPLETE CONTROL of the man of the shaft, and is CAPABLE OF CARRYING 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.

BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

**SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.**  
**E. G. DENNISTON, Proprietor.**

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

WILLIAM H. TAYLOR, President.

R. S. MOORE, Superintendent.

L. R. MEAD, Secretary.

## Refining Coppery Bullion Produced by Amalgamating Tailings.\*

NUMBER 5—CONCLUDED.

### Treatment of Residues.

These consist of leachings and wash waters, freed from silver, but containing sulphate of copper in solution; and of concentrated mother-liquor from the crystallizers.

The former, if above 15° B. (the financial limit at Dayton, as determined by experience), were concentrated. Otherwise they were run (much diluted) through a series of vats (old crystallizers arranged so as to overflow from one into another) which contained scrap wrought iron. The copper thus obtained was washed, dried, and melted into bars for use in the silver-precipitating tanks. As the leachings from all the bluestone works was run into these vats, sufficient copper was obtained to supply the wants of the refinery.

The mother-liquor left after crystallizing concentrated solutions contained an excess of free acid, and was used in dissolving copper ore in the bluestone works. No credit was given in the accounts to the refinery for this material.

### Cost of Refining.

The following figures are for the year 1876, when prices were very high:

Sheet-lead cost (delivered) a small fraction over 12 cents per pound.

The refinery was charged, at the rate of 15 cents per pound, for the copper contained in the "base bullion" produced by the mill of the Lyon company. The copper in the "white bullion" and in the bullion received from other companies was taken as payment for refining, outside companies being bound, in addition, to purchase at prevailing market rates a fixed amount of bluestone for each 100 pounds of bullion refined for them.

The price charged for acid was unusually high, owing to expensive repairs and construction at the acid chambers, which items were always included in the running expenses.

The refinery, which was in operation only a part of the time, conformed in its work to the requirements of the mill and the bluestone works.

The rate of wages, per shift of 10 hours, was as follows: Masons, \$7.50; carpenters, \$5.00 and \$6.00; blacksmith and mechanic, \$5.00 each; lead-burner, who was permanently engaged, worked wherever he was needed, and was, in fact, foreman of the chemical department, \$4.50; head men on crystallizers and dissolving tubs, \$4.00; watchmen and outside men, \$3.00; Chinamen, \$1.53; all others, \$3.50.

The refinery treated 89,394 pounds of retorted bullion (part of which was received from other mills), and produced 285,224 pounds of crystallized bluestone, and, also, on special order from purchasers, solution containing the equivalent of 16,400 pounds of crystals. From one pound of copper about 3.6 pounds of  $\text{CuO} \cdot \text{SO}_3 + 5\text{H}_2\text{O}$  were obtained.

The following statement is not an estimate, but a record taken from the books of the expenses actually incurred. It should be remarked that, in figuring the cost per pound of making bluestone, the items of *roasting, dissolving, and concentrating* are divided by 301,624, the total number of pounds of  $\text{CuO} \cdot \text{SO}_3 + 5\text{H}_2\text{O}$  and its equivalent manufactured; the

other items by 285,224, the number of pounds produced in the shape of crystals.

Under *dissolving* are included all expenses of handling the bullion after roasting; also the cost of making steam.

The figure given for *repair-material* is the

[For table showing cost, etc., see page 108.—Eds. PRESS.]

At the Omega refinery the bluestone was not crystallized,† but the sulphate of copper solutions were weakened to 20° B., and run into a stock tank, whence they were pumped by means

LEAD "STEAM-PUMP"—(Injector).

net amount after deducting old material (pig-lead, etc.) sold; that for *repair wages* is the sum remaining after charging, so far as possible, to each of the other items, the amounts belonging to it. Thus, a very large proportion

of a lead injector (called, locally, a "steam pump") to the mill for use in the amalgamating pans. Steam was furnished to the refinery from the mill boiler. The "steam pump" used (see engraving) was devised by my former lead-

PLUNGER JIGS FOR IRON ORE CONCENTRATION.

under *crystallizing* is for repairs. The wages of the lead-burner, who was permanently employed, are divided according to his work, among all the items except that of *general*.

The bluestone establishment, it should be noted, had been running for years, and most of the plant was well worn.

The item of *general* includes superintendence, office expenses, watchmen, insurance, taxes, interest, and freight on material delivered.

burner, J. L. Robertson, and was very simple, durable and effective.

† I understand that later the solutions were crystallized.

THE Anaconda mine, of Montana, proposes to run as before, in order to make 86,000,000 pounds of fine copper per year.

Two companies are actively preparing for the erection of smelting works in Reno.

## Concentration of Iron Ores.

In making charcoal-blooms washing or cleansing of the ore from adhering gangue has been practiced for many years. A sluice-box is even to-day used for that purpose in the Southern Appalachian mountains. For the Lake Champlain bloomeries hard magnetic ores are crushed with stamps and then sluiced or jigged in hand-jigs. The stamps used in the Lake Champlain region are of the most primitive kind. They consist of a trip-hammer, dropping on a perforated cast-iron plate, through which the crushed ore escapes. The crushed ore is fed into jigs without previous sizing. In jigging this ore it is allowed to pass through the bedding into the "hutch." The tailings are scraped off and washed, though they contain a large percentage of fine ore. In many instances this is regained by subsequent sluicing. Up to 1882 no attempt had been made to introduce into this branch of ore dressing the improvements adopted in concentrating the ores of other metals. At that time, however, Mr. Arthur F. Wendt, of New York, built the "Crown Point Separator," which he has described before the American Institute of Mining Engineers. We shall give the arrangement of this plant in a future issue of the PRESS, confining ourselves now to a description of the arrangement of the jigs. The cut shows the jigs. They are of the usual type of plunger jigs, the peculiarity being the means employed to vary at will the length of stroke of the plunger, and the relative speeds of this plunger on its down and up stroke.

The desired result is secured by a combination of a pair of elliptic gear-wheels with two concentric eccentrics. As commonly used, the ratio of the short axis of the ellipse to the long axis is such that the maximum speed of the down-stroke can be made from 9 to 16 times the minimum speed of the up-throw. The stroke of the plunger permits a variation at will up to four inches. There is no jar whatever in the motion. On the down-stroke the motion begins at a slow speed, increases rapidly and uniformly until the lowest point is reached, then gradually diminishes until the plunger reaches its highest point.

Thus the theoretical maximum efficiency is closely approximated. The ore and rock are lifted bodily on each down-stroke of the plunger, and drop according to gravity during the up-stroke, almost as if the particles were falling through a long stationary column of water instead of a succession of short columns. Excellent work has been done by these machines in every instance, even where the difference in gravity is not very marked.

MEADOW LAKE.—J. R. Petrie, who is superintending the new works now being built at Meadow Lake, tells the *Truckee Republican* that "it is San Francisco, not English capitalists, that are operating in the district. The new process, as it is called, is but a combination of various old processes, and he thinks there is no doubt of its success. While the ore does not give evidence of great richness, there is an abundance of it and it promises to exceed in the outcome any mining development on the coast." The latter portion of this statement may be true, but many will doubt it. In the opinion of many persons, the reason why Meadow Lake ore has never been treated with a profit is because the metal is not in the ore on which to make a profit, no matter what process is used.

\*Read before the American Institute of Mining Engineers by A. D. Hodges, Jr.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eus.

## Idaho Mines.

(Continued from last issue.)

(For the Press by our traveling representative, FRANK W. SMITH.)

## Four Hundred Level.

East 170 feet, on the same excellent-looking ore, at which length the tunnel shows a good eight-inch ore vein. Owing to an excess of water in this ground, work has been stopped eastward, leaving ore in sight. West nearly 150 feet of a tunnel with three flows stopped toward the 300 level developed less firm vein matter, but of a higher grade. Chimneys of native silver abound in these stopes, some very rich pieces being picked down by the PRESS representative. The west drift, on the level just over this, exposed the ledge some 150 feet beyond where they now are on this level. A 10,000-gallon sump drains this lower level, the water being raised by a pump similar to the one used on the 300 level. The water from this level is raised to the 200 level and taken out of the mine through a 1300-foot tunnel that taps the ledge at the 200 level from the gulch north of the mine. Ore and waste is hoisted to the surface, and the former is hauled one mile to the 20-stamp mill at Banner for treatment. The pumps of the mine lack capacity to keep the property dry, and the machinery is not in keeping with the mine. A more handsome, regular and rich vein of ore cannot well be found than this. A comparison of the Banner with the average quartz mine of to-day results in her favor. When it is noticed that over 400 feet depth on solid and regular vein matter has been made; only a few hundred feet each side of the shaft has been taken out and nine men only to the shift are worked, it is plain to be seen that the property is as yet hardly opened. Heavier machinery for hoisting, larger pumps and doubling the present force a few times, would make this mine the Banner in every sense of the word. Little, if any, blasting is required, as the vein lies between decomposed layers of porphyry and granite. At present, however, the force is adequate to keep the mill running, as only so much can be crushed in 24 hours. This mine is not a gash vein, and if there is any virtue in a regular, well-defined ledge of high-grade ore, the company has it. A Western company in charge of this mine would never stop short of going down 1000 feet further, and realizing on the many tons of ore that this management has stored in the levels now opened. A glance at the other valuable mines of this company will show the nucleus they have for a great and valuable property.

## The Crown Point and Wolverine.

This mine is nearer to the town of Banner, and the 20 stamp mill and reduction works of the company are located alongside of and below this and its eastern extension, the Wolverine. The ore body of the Crown Point is much larger than that of the Banner, and it can be worked through tunnels and dumped directly into the ore-bins of the mill from the mine. A 200-foot shaft was sunk in the porphyry 140 feet north of the vein, and a 400-foot tunnel taps the 12-foot ore body at the depth of 200 feet. The drift at the bottom of the shaft extended 140 feet to the vein, and 200 feet west and 400 feet east on the ore body developed. No work has been done on this property for two years past. The machinery was taken off this property to open up the Banner. The management, I understand, contemplates doing some considerable work on both the Crown Point and Wolverine this fall. This latter claim has not been developed much. It adjoins the Crown Point on the east, and has produced about \$10,000; bars of 90 pounds running from 900 to 952 fine, the average value of each bar being over \$1000.

## The Elmira Company.

This company consists of a number of well-to-do New Yorkers who reside at or near Elmira, New York. The capital stock is \$100,000, all taken and owned in the immediate vicinity of Elmira. The officers are: President and Superintendent, John Brown; Secretary, N. P. Fassett; Treasurer, Christopher Preswick; Trustees, E. B. Smith, W. J. Thompson, N. P. Fassett, Christopher Preswick and John Brown. Judging from the actions of the trustees, there is no lack of confidence in the management as conducted solely by Mr. Brown, who, by the way, is the hardest-working, most economical (too much so) and careful superintendent I have ever met. Mr. B. is an Eastern man and an owner and associate with Eastern non-resident partners, who are adverse to working these properties in a manner a Western company would insist on; hence the mines are being prospected instead of being worked as they would and could be by coast capital. I am surprised that some live Western mining man does not make an effort to secure this group of mines.

## Treatment of Ores.

The Elmira Company have a 20-stamp mill, furnaces, pans, settlers, retorts, etc., that, like the hoisting machinery in the Banner, has seen its best days and is entitled to a place on the "retired list;" but, like the machinery last

aforesaid, continues to do the work. The ore from the mine is dropped into the ore-bin through a trap-door directly from wagons. A Blake crusher reduces it to feeding size. After drying and salting it is fed by hand into the batteries, elevators receiving and carrying from the batteries into the hoppers over the reverberatory furnaces, after being roasted in charges of 1500 pounds. There are four furnaces, with a combined capacity of 15 tons of pulp in 24 hours. After the proper time on the cooling floors, the pulp is wheeled into the mill and deposited into four pans in charges of 3000 pounds to the pan, thence being discharged into three large settlers. After amalgamation the product is taken to a new and model retort-room adjoining the mill, where it is melted, weighed, assayed and marked for shipment into

## Banner "Tailings."

The Elmira Company board their men. There is not much prospecting going on about Banner.

The Elmira Company have 26 men on their pay-roll.

Only a few men are kept at work all winter at Banner.

The mail is carried in on snowshoes during the winter months.

Miners are paid \$4 per shift of 10 hours. Board is \$1.25 per day.

The Silver Chief is working a day and night shift of seven men.

The fare from Banner to Idaho City is \$3; to Boise City, \$8; to Kuna, \$10.

The Banner mine was discovered July 6, 1864, by Jess Bradford and James Carr.

The Crown Point has produced \$107,000. A run of 1100 tons of this mine netted \$100,001.

A few Chinamen are working the river bars of Beaver creek and the old placers of Gold Hill near Banner.

Charley Magee runs a tri-weekly accommodation stage and wagon between Banner and Idaho City.

A California, Colorado or Montana company would work the Banner group to their full capacity, and all winter, too.

Assays from the Bullion and Imperial, near Banner, run as high as \$1500 per ton. Thos. Graney, et al., will work the properties this season.

A small force of underground miners worked all last winter on the Elmira Company's mines. The mill closes down about November 15th every winter.

The Golden Gate, 74 feet south of and parallel with the Banner, shows a four to ten inch vein; nearly 100 tons recently taken out went \$75 per ton. Over 200 feet has been developed on this vein.

Tim Carroll, County Recorder, was at one time foreman of the Banner. While acting as such he was caught in a snow-storm and lay five days and nights in the snow without fire, food or water. He lost both legs below the knee.

## The Silver Chief.

This mine is the first western extension of the Banner. It is owned by a Joliet, Ill., company, and is in charge of James Monroe, superintendent. The development as yet has been very meager, and consists of a two-compartment shaft down 180 feet. The shaft was put down 45 feet south of the ledge, the dip of the vein bringing it under the shaft at 170 feet. At this point the vein is of the same size and quality of the Banner. After going down 10 feet on the vein, a 60-foot drift was driven in west, all on ore. At this point water came in so rapidly that work was abandoned here and a force of men put on the east end of the Chief, working from the tunnel of the Banner, that taps the east end of the Chief some 70 feet below the bottom of the two-compartment shaft. They are now up 30 feet, stopping toward their shaft and taking out good, fair-grade ore, with a 6-inch vein that gets better as they open it up. The ore taken out on this level heretofore averaged \$109 per ton. The hoisting power of the shaft is a whim and bucket (horse power). They have a good ore dump that will go over \$100 per ton. This property is a good one, and needs only machinery, elbow grease and a little money invested without waiting to get a string on the output before putting up to properly work the mine. If the Joliet company or the Elmira people think they can work mines with prospecting machinery, and expect to make bonanzas out of mines by prospecting instead of developing them, they will never realize their expectations. The officers of the Silver Chief are: President, Geo. H. Monroe; Secretary, Geo. J. Monroe, of Joliet; Treasurer, James Whitten, of Wilmington. The Golconda mine, also in the Banner district, belongs to this same company. It has a 5-stamp mill on. Development consists of but a 50-foot shaft. Owing to too much water, work was stopped. They will likely do some work on this property this fall.

## Payette River Mines.

Three miles north of Banner a district known as the Payette River district has been prospected to some considerable extent. The formations are trachyte and granite, the ledges being heavy in black sulphurets and milling about \$125 per ton gold. A 200-foot tunnel run into the side hill out two veins; the first 100 feet deep, the other 35 feet deeper. Both veins are said to be nearly ten feet thick, and they dip toward each other at an angle that indicates their coming together. A San Francisco firm recently offered \$40,000 for these properties but did not get them.

## How to Get Here.

The following routes are the easiest and most practical to reach this part of the Territory: Union Pacific and Oregon Short Line from the East; South, Omaha and Denver, or the D. & R. G. and the Short Line from Denver via Salt Lake to Kuna station. From the Northwest the O. R. & N. and the Oregon Short Line to Kuna, thence by stage to Boise City.

## California, Oregon &amp; Idaho Stage System.

The above company runs daily stages from Boise City to the camps hereinafter named, charging fare as follows: Idaho City, \$5; Centerville, \$6.50; Placerville, \$7; Silver City, \$8; Kuna, \$2; Emmettville, \$3; Payette, \$5; Falk's Store, \$4. The traveler can add these prices to the fare from their starting point to Kuna, and thus get the cost of visiting Boise basin or vicinity. I go hence to Silver City, from which I will write you next week.

## Mining on the Lower Klamath.

EDITORS PRESS:—The mining season on the lower Klamath from Orleans Bar down is about closed, and it has been a successful season for this section. A few claims are still running, but will soon shut down. Much more interest is being taken in the gravel deposits below Martin's Ferry, and a number of locations have recently been made on well-known and extensive gravel deposits, with a view to operating the same the coming season. Miners are beginning to appreciate the fact that the debris in junction is not a thing of terror on this river, and that the nearer the coast they get the better the water holds out. There are a number of privileges here in this immediate vicinity, covering extensive pay gravel, that will afford ample water the year round.

But probably more important than this is the discovery of both silver and chrome here near the river and within 12 to 15 miles (air line) of the coast. Ore has been found carrying \$27 a ton of silver, and the country seems to bristle with chrome of an unusually high grade, and both are surrounded by and lie contiguous to unexcelled means for working and transportation. The Klamath river offers a universal and never-failing avenue through which transportation can go forward to deep water at nominal rates. There is a large country to the northward of the Klamath, and near the coast, which is a virgin field to the intelligent prospector, and the fact of its accessibility ought to commend it to those seeking new fields of research for the precious metals. There is an immense deposit of brown hematite of exceptionally high grade lying north of and near the river and within a few miles of the coast, but I suppose the growing probability of iron being largely supplanted by the use of aluminium will detract essentially from the value of such a mine, however favorable the conditions might be to its advantageous working.

The mammoth ditch from Red Wood creek to Gold Bluffs, projected by Dr. Hood, is still undergoing the preliminary of adjusting the different test surveys. It is thought the active work of excavation will commence this fall. The beach mines have not turned out for a number of seasons, though the work is kept up in a small way at different points.

## Klamath Bluffs.

OBSERVER.

## Quartz Grinders Again.

EDITORS PRESS:—Referring to the PRESS correspondence between Mr. Louis Blanding and the "Old Man of the Mountains," will you kindly allow an outsider wholly disinterested, except as an aged miner and stamp-mill superintendent, to make a few remarks on that controversy? I have no prejudices for or against one kind of mill over another. If we could only get a thoroughly effective, economical roller or grinding mill to fully take the place of stamps, surely it would be a great blessing to the mining community.

I regret to see that "the old man" comes before your readers merely as a captious critic. He offers no testimony whatever in favor of stamps over grinders. His whole argument, so far as it is entitled to the name, is made to hinge upon his age. I have known old farmers who would not adopt new implements or machinery because their fathers did not possess corresponding advantages, and yet got along very well indeed. "The old man" says quite clumsily: "It is the facts and brains presented that interest the public." Just so; if he has made your readers a presentation of his brains, I suspect few have got a glimpse of them. He has offered no facts in support of his opinions, except that he "knows exactly what he is talking about," and that does not seem to be a fact, after all. On the "little knowledge" point he is quite "smart," but it is not "smartness" that is needed when a grave subject, bearing on the success or non-success of a great army of practical miners, is under discussion.

If he has a personal grudge against Mr. Blanding, let him expatiate over it in some local journal; but in writing for the PRESS, plain, experimental data are necessary, and 36-year-old shoe-and-die assertions are worth very little. Elihu, the Buzite, felt called upon to rebuke vapid senility, and though I am not a young man as he was, I follow his excellent example.

CENSOR.

## Washington Territory Mines.

EDITORS PRESS:—The output of first-class ore from the Old Dominion mine has been up to the standard during the past month, and has all appearances of keeping up her reputation for some time to come. One carload, or 20 tons, a week has left the depot from Spokane Falls bound for Omaha, where it will turn out on an average nearly \$250 a ton.

During this time, four times as much second-class, or \$75 ore, has accumulated on the dump awaiting much needed reduction works which the prospector and miner have waited so patiently for. There must be between 3000 and 5000 tons of \$75 ore on the dump at present. The lower workings look better than other parts of the mine, there being large bodies of the richest of our sulphide and chloride ores.

The Ella, joining the Old Dominion on the north, is being developed by a perpendicular shaft with the intention of running a crosscut at a depth of 100 feet. This is one of the cheapest mines worked on the mountain, the depth gained being one foot a day of 10 hours for two men at the drill. A double compartment shaft is being timbered with tamarac—a tree very plentiful among the mines. The Ella is an east and west vein at the surface in crystallized limestone, carrying a net-like formation of manganese. The ore is of a carbonate nature with a large percentage of oxidized iron and some galena and sulphide, assaying at the smelter about \$100 a ton. The ore will average two and a half feet wide. Sixty tons were shipped from a 25-foot shaft, and as much more left on the dump.

E. E. A.

Colville, W. T.

GOLD MINE IN HIS EYE.—A remarkable case of surgery occurred last week in the practice of Dr. J. L. Mayon, of Sutter Creek. A man named Thomas Hackett, 50 years of age, applied to him for relief, stating that his left eye has been a source of constant pain to him for the last three months. A slight examination of the optic—which had been blind for 17 years—showed that a foreign substance was imbedded in the eye-ball. An operation was performed, resulting in the extraction of three pieces of gold quartz, the largest about the size of a bean, and weighing eight grains. The patient experienced immediate relief on getting rid of the load. It seems that 17 years ago, while working in the mines of Nevada county, a piece of rock struck him in the left eye, entirely destroying the sight. The real state of fact—that the quartz had buried itself in the ball of the eye—never dawned upon the attending physician. After a time, nature being unable to throw off the foreign body, formed an independent bag or cyst around it. In other words, it became isolated from the system, although imbedded in it, and its power to cause pain was thereby destroyed. For 17 years the man had carried it in his eye, never dreaming of its presence there. The eye is one of the most sensitive organs of the body, and the fact of the quartz becoming encysted in that organ at all is a remarkable, if not unprecedented, occurrence. Latterly, nature again made an effort to expel the invader, and actually forced the quartz through its cyst, and this led to its discovery and removal as above stated. The quartz was ordinary gold rock, with a large percentage of sulphurets, and specks of gold visible to the naked eye. Hackett is joked about carrying a gold mine in his eye for 17 years without knowing it.—*Amador Ledger*.

THE CLEARWATER COUNTRY.—In a recent conversation with a gentleman regarding the southern part of Shoshone county, we expressed some surprise that the mountains along the forks of the Clearwater and their tributaries had never been extensively prospected for gold. We were told a few locations were made years ago when the placer excitement began to decline, but that hardly any work was done on them, and none amounting to anything except one in Democratic gulch, a tributary of the North fork of the Clearwater. On this a small mill was built, and we are told that it is still in operation. Silas W. Moody, our last joint councilman, and now Territorial controller, is said to be a part owner of the mine and mill. The stampede to the Boise basin nearly depopulated the southern section of the county, then the only part that contained a white settlement, and practically put a stop to the prospecting for quartz which had then only fairly begun. Scarcely anything has been done there since '67 or '68, when there was a little mining on Moose creek, another tributary of the North fork of the Clearwater, which heads in the mountains that constitute what is called the St. Joseph divide. Many believe that these mountains contain numberless rich ledges and that in the near future the region will prove a veritable paradise for prospectors. This season Cœur d'Alene prospectors have found fine-appearing float on the divide between the South fork of the Cœur d'Alene and the St. Joseph, and it is reasonable to believe that there are good ledges along the divide first mentioned.—*Cœur d'Alene Record*.

DR. F. M. ENDLICH, formerly superintendent of the Lake Valley mines, N. M., has patented a process for treating ores—especially copper. He claims that by his method copper mining may be made profitable in the Southwest.

## MECHANICAL PROGRESS.

## Progress in Saw Manufacturing.

The immense extent to which the lumber business has been carried in this country, and the millions of dollars invested therein, has kept the inventive mind of our mechanics constantly active in devising new and improved methods for manufacturing lumber, especially in the construction of saws. In 1830 there were only three saw manufactories in the United States. In 1880 that number had increased to 89. The value of the annual make of saws in the United States is \$3,619,718, of which the State of Pennsylvania produces nearly one-half. The saw is second in importance only to the ax, and in some form or other has probably been used quite as long. The first saws were doubtless very primitive in their construction—nothing but flat pieces of metal, simply with notches cut into the edge.

The best known, because the most widely used of all varieties, is the buck or wood saw. In this the Americans have discarded the use of the stick and twisted-cord strainer, formerly so conspicuous, and rods with a nut and screw are substituted. The blades of these saws are furnished either with the ordinary inclined tooth or with the double cutting form. The next best known is the hand-saw of the carpenter, which, in its various forms of rip and cross-cut, is indispensable in building operations.

For a long period all saws were of the reciprocating pattern, that is, made with a flat blade and having a straight edge, and it was not until the year 1790 that the scope and power of the saw was largely increased by the invention of the circular or "buzz" saw. These saws are now made with either solid or removable teeth, and in their adaptability to machinery driven by steam power, they are of great value and importance to all industries. Previous to 1830 the United States was almost entirely dependent upon foreign manufactories for a supply of saws. At that time it is estimated the value of the saws made by the three saw manufactories did not exceed \$5000 per annum. In that year, Mr. Charles Griffith, who had been engaged in the manufacture in Great Britain, established himself in Boston in the making of circular saws. Since that time the ingenuity of American mechanics and the enterprise of American capital have established many concerns in this country, one of which is the largest saw manufactory in the world, whose products find ready sale in competition with English goods. American steel is also used in their manufacture, and Europe may learn from us in saw-making. All saws are hardened or tempered in oil, and the forms and sizes of the teeth depend upon the quality or substance to be cut. Iron bars, shaftings, etc., are cut into lengths by a steel circular saw, which revolves very rapidly. The iron is presented to the saw red hot, and a bar two inches in diameter can thus be cut through in a few seconds. The swaging, or spreading of the teeth to give clearance in cutting; the filing or sharpening of the points; the setting or the bending of the teeth, and the well-known process of gumming, are all operations which require skill, and upon the accuracy of which depends largely the value of the saw. The entire process of making a saw from the raw material to the polished finish is based upon scientific principles, and, with the aid of ingenious machinery, is performed with a wonderful degree of accuracy.

**SKETCHING FOR MECHANICS.**—While the value of a knowledge of mechanical draughting to a mechanic is indisputable, there is a sort of free-hand drawing or sketching that is also useful. The faculty for its practice may be innate, and in that case but slight instruction is necessary to enable its possessor to illustrate his thought far better than he could impart it verbally. But even those whose natural tendency does not impel them to sketching as explanation can get enough facility by practice to make themselves understood readily. Probably nothing is more difficult to explain and exhibit by words alone than mechanical construction and mechanical movement. It is not only difficult for the narrator, but also for the listener. The memory must hold all the points of the information in contact ready to make a completed idea at the climax. But an appeal to the eye, however crudely made, presents the entire image at one view without any laborious action of the mind. And it is a noticeable fact that those mechanics who are of an inventive, improving and originating turn of mind are most apt with pencil and paper, or chalk and slab. To them the mechanical idea has received a form in their own mind, and by a partial representation they seek to impart their knowledge to others. The practice of sketching, as illustrative of verbal statement, is an excellent one for mechanics generally to acquire. Shop work demands the ready hand at sketching. There are many jobs which do not require the preliminary preparation of the draughting-room that are greatly expedited if the foreman has a facility with pencil, crayon or chalk.

**A GIGANTIC STEEL FORGING.**—One of the most remarkable efforts at heavy forging was recently effected at the works of Schneider & Cie, at Le Creusot, France. The work turned out was a revolving turret or fighting tower for the Italian armor-clad *Lepants*. A huge block of steel was first cast, which weighed

65 tons. This ingot was worked down to a diameter of six and one-half feet, then bored out, placed upon a mandrel and forged to an outside diameter of 10 feet, with an inside diameter of 7 feet 11 inches. The walls of the turret when completed were 12½ inches thick, and 4 feet 9 inches high, weighing 30 tons. It is intended to be occupied by the captain of the ship in battle, and not for the reception of cannon. It is the first fighting tower that has ever been made in one single piece, and it is said that no other firm in the world possesses the necessary appliances for such a construction.

**WIRE PAINTING MACHINE.**—Barbed and other wire fences often require a renewal of the paint usually placed upon them before sale or use, and hitherto the cost of such work has been great, for self-evident reasons. Mr. R. Quatermess, of Molin, Kansas, has invented a machine for doing that work which is very efficient, and which may be operated either after the wire has been placed in the fence or as it is coming from a reel. The machine is carried along the wire by two men upon opposite sides of the fence or wire. Its weight rests upon the wire and it is worked by the operators moving along. The vessel in which the paint is placed is carried by two handles, which may be raised or lowered, and held in any desired position, according to the height of the wire to be painted. The wheel is journaled in bearings which may be set higher or lower, as the quantity of paint in the vessel may require. In a groove in the periphery of the main body of the wheel are teeth upon which the barbs of the wire catch, thereby rotating the wheel. Beyond these teeth are fixed annular brushes. The surplus paint is removed from the brushes by a properly-arranged wire, and paint from the sides of the wheel is removed by wipers, which prevent the paint from being wasted by adhering to the sides, or by being thrown from the vessel by centrifugal force as the wheel revolves. The machine is carried along the wire, the operators simply walking along the fence, one at each side, when the wire is thoroughly painted by the revolving brushes. Should the bristles of the brushes become set or inclined to one side, the wheel may be reversed in its bearings, so as to operate the other way. It will be seen that by means of this machine fence wires may be painted thoroughly as rapidly as two persons can walk, and with no waste of paint. Should the fence wires be placed too closely together to admit of carrying the machine upright, it may be inclined to one side.

**LUBRICATION OF STEAM ENGINES.**—It has been a long time the practice of horologists to use graphite as a reducer of friction, in even the most delicate pieces of mechanism. In blowing engines, also, if the gearing is copper, graphite is the only lubrication. These facts led M. Thoma, of Memmingen, to try a mixture of graphite (prepared by decantation) and hog's lard, first in the stuffing-box of a pumping engine, and subsequently upon a steam engine. The result was very satisfactory; the only care requisite was to keep up the quantity of graphite in the mixture, as otherwise it becomes too fluid. The next experiment was made with a paste of graphite and water. The result was equally good; the slight escape of steam into the stuffing-box was sufficient to keep the graphite moist, and the lubrication seemed quite perfect, although there was no fatty matter present.

**BOILER NOTES.**—Hard wrought iron is weakened from 15 to 30 per cent by punching.

In punched holes the small sides of the holes should come together.

Drilled holes should have the edges chamfered.

Friction due to this tension would be about 7000 pounds per square inch of riveted section.

The usual diameter of rivets in hand riveting varies from one-half inch to seven-eighths inch.

In machine riveting they may be used up to one and one-fourth inch diameter.

Maximum efficiency of single riveted joint equals two-thirds strength of plate.

Maximum efficiency of double-riveted joint equals four-fifths strength of plate.

When the lap exceeds three times the diameter of rivet, the caulking is apt to open the joint unless done very lightly.

**IMPORTANCE OF THIN-BLADE SAWS.**—The Germans use at the present day among their furniture-makers, carpenters and joiners, 13 different varieties of saws, each one of which has its own peculiar size of the teeth, as well as a different relation of the teeth to each other. How important the thin saw-blade is, not only as a means to save power, but also as a means to save wood, can be seen from the following: A log of walnut, 4 meters long and 1 meter diameter, cut into 20 pieces by the new horizontal saw-frame, saves 30 millimeters of wood when compared with the cutting of the old-fashioned vertical saw. This is equal to a profit of \$9 to \$12. For Germany, where annually 100,000 cubic meters of this wood is used in various industries, this would represent a saving of \$37,500 to \$50,000.

**TO PRODUCE A RED STAIN ON WOOD,** the wood is plunged first in a solution of one ounce of curd soap in 35 fluid ounces of water, or else is rubbed with the solution, and then magenta in a state of sufficient dilution to bring out the tone required is applied. All the aniline colors behave very well on wood.

## SCIENTIFIC PROGRESS.

## Science in America.

A Compliment Paid to this Country by a Prominent Englishman.

In his pleading for more State recognition of science, Sir Lyon Playfair, the President of the British Association at Aberdeen, pointed out the present activity of Germany and France, and especially of the United States:

"Both France and Germany make energetic efforts to advance science with the aid of their national resources. More remarkable is it to see a young nation like the United States reserving 150,000,000 acres of national lands for the promotion of scientific education. In some respects this young country is in advance of all European nations in joining science to its administrative offices. Its scientific publications, like the great paleontological work, embodying the researches of Professor Marsh and his associates in the geological survey, are an example to other Governments. The Minister of Agriculture is surrounded with a staff of botanists and chemists. The Home Secretary is aided by a special scientific commission to investigate the habits, migrations and food of fishes, and the latter has at its disposal two specially constructed steamers of large tonnage.

"The United States and Great Britain promote fisheries on distinct systems. In this country we are perpetually issuing expensive commissions to visit the coasts in order to ascertain the experiences of fishermen. I have acted as chairman of one of these royal commissions, and found that the fishermen, having only a knowledge of a small area, gave the most contradictory and unsatisfactory evidence. In America the questions are put to nature, and not fishermen. Exact and searching investigations are made into the life history of the fishes, into the temperature of the sea in which they live and spawn, into the nature of their food and into the habits of their natural enemies. For this purpose the Government gives the co-operation of the navy, and provides the commission with a special corps of skilled naturalists, some of whom go out with the steamships and others work in the biological laboratories at Wood's Hole, Massachusetts, or at Washington. \* \* \* The practical results flowing from these scientific investigations have been important. The inland waters and rivers have been stocked with fish of the best and most suitable kinds. Even the great ocean which washes the coasts of the United States is beginning to be affected by the knowledge thus acquired, and a sensible result is already produced upon the most important of its fisheries. The United Kingdom largely depends upon its fisheries, but as yet our own Government has scarcely realized the value of such scientific investigations as those pursued with success by the United States."

## History of an Ancient Cyclone.

Mr. John J. Campbell, of Rockville, Indiana, has succeeded in the very original work of tracing the course of a cyclone which must have passed over that portion of the country more than 300 years ago. The course of the storm was traced by means of what he calls "tree-graves"—that is, the little mounds which a tree makes when it is uprooted and allowed to decay upon the spot upon which it fell. The earth thus turned up by the roots, with the decayed root itself, will generally form quite a large mound, which is often taken for an Indian grave; hence "tree-graves." The date of the storm in question, as communicated by Mr. Campbell to the *American Naturalist*, was marked by noting the age of an oak which had grown on the top of one of the "tree-graves." Its course was found by inquiring where other "tree-graves" had existed or had been observed in the past, and was traced in a belt about 1000 feet wide for 15 miles. Where the "tree-graves" are numerous, as in the path of Mr. Campbell's cyclone, they are supposed to mark the place where a fierce battle has occurred. In the wild forest these marks are, though more than 300 years old, as well preserved and as distinct in outline as many made by trees that have fallen recently. But if the land is cleared and cultivated, they disappear in a very few years under the action of the plow and of exposure to frost and rains. The preservation of the little mounds in the woods, which under the continuance of the conditions might last for 5000 or even 10,000 years, is due to the thin coating of forest leaves that lie upon them. Says Mr. Campbell: "The leaves act as shingles in shedding the rains, so that they are not washed or worn down by the falling rain or melting snow. The frost does not penetrate through a good coating of leaves, and therefore they are not expanded and spread out by freezing and thawing. I can see a great difference between the mounds in the wild forest and those on land that has been set to grass and pastured a few years. The tramping of stock, and the frequent expansions from freezing, which the grass does not prevent, flatten them perceptibly. The grass, however, does preserve them against rain-washings."

**EARTHQUAKE WAVES.**—One of the most extraordinary phenomena connected with earthquakes is the effect which they have upon the ocean in the raising of great sea waves, sometimes of almost incredible height. The great wave which reached the coast of Spain and Portugal in

1761 was 60 feet high; that at Callao in 1724 was 80 feet, and the greatest on record is reported to have reached Lupatka in 1737 at the enormous elevation of 210 feet. No doubt but that report must be taken with many grains of allowance. These waves are often more destructive on land than the actual shocks; the influx is usually preceded by an outflow, which, in fact, acts as a warning. One of the most remarkable effects is the distance to which these waves are propagated as "great waves," *c. g.*, entirely across the Pacific. Thus most large earthquakes on the east or west coast of the Pacific produce waves which are recorded on the opposite coast about 24 hours after. As to prediction of earthquakes, nothing certain is yet known. In many cases there are noticeable changes in springs and wells preceding earthquakes. One useful warning is, however, obviously possible, viz., the report of an actual earthquake on one side of the Pacific could be at once telegraphed to the other side, thus giving 24 hours' warning of the probable advent of a great sea wave.

## Earthquakes and Other Earth Movements.

We are accustomed to think of the land of the earth as something solid and fixed, and, as a testimonial of this impression, the Latin phrase, *terra firma* (firm land, or solid ground), has been naturalized in the languages of nearly all civilized people. On the other hand, we speak of water as unstable. But the geological history of the earth, and the more careful observations of modern times, have taught us that these ideas do not correctly represent the qualities of the land masses and water masses of the globe as compared with one another. The ancient shore marks on the continents, and the phenomena of elevation and subsidence that have been observed in historic times, confirming their evidence, show that the land and the ocean are continually changing their level as to one another; and it has further been made evident, by experiment, as well as by *a priori* reasoning, that it is not the ocean that changes, but the land which undergoes alternate movements of elevation and depression. An earthquake shock is a phenomenon well adapted to destroy the faith of any person who feels one in the fixedness of the earth; and such, by the evidence, is the effect for the time on all who experience these shocks. Even the light pulsations which sometimes pass over parts of the United States occasion panic and excite a momentary impression that everything is falling over or sinking away, while the more violent shocks that are felt in earthquake-visited countries produce indescribable terror; and such catastrophes as those historical earthquakes of Lisbon and Caracas, and the more recent ones of Ischia and the Strait of Sunda, amount to a demonstration that the reason for such terrors is real, and that the continents also cannot escape the general law of change and perishability.

Earth movements—the name by which these phenomena may be most conveniently described—are various, and comprise, so far as they are now considered, earthquakes, or sudden violent movements of the ground; earth tremors, or minute movements which usually escape attention by the smallness of their amplitude; earth pulsations, or movements which are overlooked on account of the length of their period; and earth oscillations, or movements of long period and large amplitude—like the shifting of levels of land masses—which attract attention from their geological importance. Some of these movements have only recently begun to attract attention. They are all intimately associated in their occurrence and their origin.

**AFTER SUNSET GLOWS.**—From his observatory, at Colmar, M. Faye has noticed the phenomena of crepuscular lights at an altitude far higher than that of the terrestrial atmosphere. Without deciding on the merits of the different theories advanced to explain the origin of the after-glows, he considers that electricity alone would be capable of retaining at such an altitude the particles of matter producing the effect, whether these articles had a terrestrial eruptive source or had come from interstellar spaces.

**FERRIC SULPHATE** decolorizes indigo in the same manner as ferric chloride or potassium ferricyanide. In preparing iron mordants by the action of nitric and sulphuric acids upon coppers, indigo cannot be used to show the disappearance of the nitric acid, as the mordant formed acts itself upon the coloring matter.

**MODERN CAVE-DWELLINGS.**—It appears that there are inhabited cave-dwellings in Saxony even to this day. They are dug in a sandstone hill, have different rooms, dark and light, as well as chimneys, windows and doors, and are said to be very dry and habitable.

**OIL-CLOTH** may be improved in appearance by rubbing it with a mixture of a half-ounce of beeswax in a saucerful of turpentine. Set this in a warm place until they can be thoroughly mixed. Apply with a flannel cloth and then rub with a dry flannel.

**TO MAKE BAY RUM** from the bay oil, take 10 fluid drachms oil of bay, one fluid drachm oil of pimento, two fluid ounces acetic ether, three gallons alcohol and two and one-half gallons water. Mix, and after two weeks' repose, filter.

## MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

## CALIFORNIA.

## Amador.

**PACIFIC.**—*Ledger*, August 7: At the 1500-foot level, the ore body in size and richness exceeds anything heretofore met with in this famous mine. It is said to be 30 feet wide, without any barren or waste rock in it.

**KENNEDY.**—Sinking is finished at the Kennedy. The shaft has a total depth of 975 feet. They are now engaged in cutting a station at the 950 level, preparatory to drifting. The machinery for the mill is expected to arrive this week. The frame-work and castings will all be shipped from below ready fitted, while the outside lumber will be obtained from the local sawmills.

## El Dorado.

**SHAFT.**—*Placerville Observer*, Aug. 4: A contract has been let to sink the main shaft at the Springfield mine 200 feet deeper. The shaft is now down 1200 feet, and the ore continues of a high grade. In fact, we believe the Springfield the best mine in the State. A mining expert, who visited Georgetown the first of last week, reports active work at the mine of Dr. Spencer, with a promise of good results. J. H. Bradley was over to the North Side last week, and reports considerable activity in mining. Hulburd, of the *Gazette*, has, in the opinion of Bradley, one of the best mines in the county, if he can get it opened.

**INDIAN DIGGINGS.**—Seeing that items from many places in the county are sent to the papers, this place, too, can furnish a few, and for good average mines cannot be beat in the State. Hale & Baughman made a partial cleanup, and are well pleased. They are still pining, and will continue so long as water holds out. Cape & Horrell have cleaned up, and made a success of it. Kimball & Dater, of Placerville, who purchased the Lamb mine, and who have been running a bedrock race for more than a year, have broken through into the gravel, which is quite rich.

## Nevada.

**DELHI.**—*Nevada City Herald*, Aug. 4: The latest news from the Delhi mine is that a rich strike has been made. For several months the company have been running a tunnel to tap the vein at a considerable depth below the old workings. It was feared by some that the chute of rich ore which was worked out in the upper tunnel would not go down very deep. A day or two ago the vein matter was reached and a sample taken from a stringer of quartz on the foot wall prospects at the rate of over \$600 per ton. The formation is as large as above and there is a good showing of ore, but the superintendent thinks that where the tunnel cuts the ledge the ore chute is not yet properly formed. When a drift shall be run on the ledge no doubt a bonanza will be found.

**WILLOW VALLEY MINES.**—*Transcript*, Aug. 6: The Buckeye has a ledge from four to six feet thick and is paying well. The new five-stamp mill runs steadily and does its work admirably. The drain tunnel at the Neversweat is being pushed ahead through hard ground, and will soon reach the ledge. The lessees of the Deadwood are reported to be taking out some good ore. The Hussey is idle on account of litigation between the owners. At the Rising Sun nothing is being done just at present. The owners are poor men and are necessarily compelled to proceed slowly in its development.

**MEADOW LAKE NEWS.**—*Foothill Tidings*, Aug. 9: Frank Walker came down from Meadow Lake district a few days since, and he gives us the following information concerning a mill that is being put up there by San Francisco parties, and which, it is thought, will be successful in working the ore. The machinery consists of the following items: First, a rock-breaker or crusher; second, a large cast-iron machine which looks as though it were to be used to grind the ore; third, two iron cylinders about six feet long, probably rotary ore-roasters; fourth, a concentrator of new device; fifth, a small dynamo and electrical apparatus; also numerous shafts, pulleys, pipes, etc. When Mr. Walker left Meadow Lake there were some 15 men employed in and around the mines and mill. Walker will not go back, as he and several others struck work because of a reduction in wages. It seems that the building of the mill is in the hands of a contractor, and that men who were hired at \$3.50 per day were forced to accept \$3 per day; men hired at \$3 were paid only \$2.50, and so on. About a week since, when payday came around with the results as above stated, several of the men, including Walker, quit work and returned to their respective homes. The men say that when the next payday came around they would have probably suffered another reduction, as the contractor had things all his own way.

**A RICH STRIKE.**—*North San Juan Times*, Aug. 7: A rich strike was made in the lower tunnel in the Delhi mine on Friday of last week. About eight months ago the Delhi Company, seeing that the rock in the main tunnel must soon give out, began running a tunnel 200 feet lower down the hill, expecting to strike the ledge when in about 300 feet. In this they were mistaken. In the meantime the pay ore on the main level gave out, and the men were put at work in the Puzzler claim, 1000 feet west of the Delhi, and the mill has been kept running on rock from that claim for several months past. On Wednesday of last week the men driving the lower tunnel at a distance of 700 feet encountered a stringer which assayed \$650 per ton, but it was soon lost again. On the following day it was again found, and on Friday a second stringer was encountered which assayed \$800 per ton. These stringers have now joined and form a ledge 2½ feet wide, which width increases as the work is pushed forward. As the mill is situated 200 feet above the tunnel, some means will have to be devised to get the ore to the mill. It was the intention of the company some time ago to move the mill down below this tunnel, but whether this will be done or a tramway built we are not advised. Supt. Spafford celebrated the strike on Wednesday evening last by giving the employees a fine banquet. A company composed of Martin Burth, Ed. Powers and Peter Graham is de-

veloping a ledge of quartz under Buckeye Hill, and is encouraged with unusually good prospects. And still the good work goes on. Ere many months have elapsed there will be six or eight miners working on this ledge, and extracting the precious metal, and that with a complement of men that will discount our former hydraulicers.

**THE MABEL MINE.**—*Transcript*, Aug. 7: The Mabel drift mine, just above North Bloomfield, is working about 40 men and pays well. There is an incline of about 250 feet and the tunnel is 500 feet, more or less. There is about 1500 feet of the channel yet to work, and at the present rate of yielding it will turn out a large quantity of gold. This is the mine which was opened by the late R. P. DeNoon.

## Placer.

**GOOD PAY.**—*Placer Argus*, Aug. 5: Good pay has been struck in the Doig mine, and Robinson and Shurtleff are happy. They took out over \$1000 last Saturday from a pocket of decomposed quartz. On Monday about \$10,000 was taken out, if report speaks truly, and next day a still greater sum. There are four men employed at the mine, including the two owners just named. The mine is about half a mile from Ophir, being situated near the Belvoir, formerly called the Boulder. At the old St. Patrick mine, also, some very good rock is said to have been taken out lately. Shurtleff and Shofer are operating there.

**RICH ORE.**—*Nevada Transcript*, August 7: Some remarkably rich ore has recently been taken out of the Rising Sun and Big Oak Tree mine, consolidated, near Colfax. Mr. Werry, one of the owners, on Sunday last showed Jesse Clemens and the *Transcript* man two small pieces, one of which is estimated to contain \$20 and the other \$50. It is just such quartz as carries the pioneer miner back to the days of long ago when he sees it. About 40 men are now working in the mine. The 10-stamp mill, recently rebuilt, runs nicely. The new hoisting and pumping machinery is about ready to start up. The owners are happy, the indications being that they have a first-class property.

## San Bernardino.

**THE ZARAGOZA.**—*San Bernardino Index*, Aug. 6: This morning we received, through the kindness of Mr. Knight, a sample of the ore taken from the Zaragoza mine, which lies between Holcomb and Bear valleys, and is owned by the Metzgar Bros. The sample sent us was taken from the mine at a depth of 33 feet, and is a splendid piece of free-milling gold quartz. Gold can be seen with the naked eye, and when a glass is used it fairly glitters with fine and coarse gold. We have not had an assay made, but should judge that the ore would mill not less than \$300 per ton. Mr. Metzgar writes that this is a fair sample of the ore that is now being taken out of the mine. If this be true, the boys have indeed struck a bonanza this time sure. He says: "The mine continues to improve the deeper we go, and we are more than pleased with the prospect. We struck another ledge on the same ground, about 100 feet from the one we are working, that is larger and bids fair to equal it in richness. We have another claim also that has a ledge of from two to three feet that looks as though it will prove a bonanza." Mr. Knight, who brought in the ore, says that the Zaragoza mine lies right in the heart of the old placer diggings, and was discovered by some Mexicans while placer mining. Mr. Knight is also of the opinion that much of the gold found in the placer mines came from the ledges now owned and being worked by the Metzgar Bros., and he has every reason to believe the mine will continue to turn out rich ore. We hope his opinion is correct, for it will cause the old camp to boom again as in the good old days gone by, and will bring more men and money into our county. There is every reason to believe that to-day there are just as rich gold mines in Holcomb and Bear valleys and vicinity as there were 20 years ago when mining paid handsomely there.

## Shasta.

**MILL.**—*Shasta Co. Democrat*, Aug. 4: Jack Conant will have a five-stamp mill crushing ore on Squaw creek inside of two weeks. Reily & Matthews have opened an eight-foot vein on the Black Bear, Squaw creek, and the ore prospects big. Tom Green's new five-stamp mill is doing splendid work, and Tom's bullion cleanups have increased accordingly. Bell & Hopping have purchased a larger engine to drive their milling machinery on their mine in Old Diggings. Sunderhaus, Busch & Co. are building a new house on the Snyder mine; they are also working three shifts in the mine, making an average of five feet a day.

**IGO.**—*Cor. Shasta Courier*, July 31: Messrs. Lytten & Bennett have leased the Continental mine and mill, and are putting things in shape for active operations. The starting up of the Chico mill has been delayed by a defective piece of machinery, together with the rapid shrinkage of the water supply during the hot weather of the past week. Good ore is being taken out at the mine. O. Engle is continuing the Dayton tunnel along the ledge, to tap the ore chimney worked on the surface. E. L. Balou's arastra is running on Manzanita ore. The Meek arastra is running on Atlantic ore. The good ore still holds out. F. Shirland is also getting out a run from one of the Atlantic series of ledges. J. Blank is running his ore through J. P. Wright's arastra. Water for the arastras is still plentiful, although there is some growling where water for power and irrigation is in demand at the same time.

## Sonoma.

**GREAT EASTERN MINE.**—*Sonoma Democrat*, Aug. 7: The Great Eastern and Mount Jackson quicksilver mines, near Guerneville, both operated by one corporation, are now running in full force and shipping large quantities of quicksilver. The manager states that the price received for the last lot of quicksilver sold was the highest price that has been paid in seven years, which was 36 cents per pound, or \$32.40 a flask. He anticipates that the price will go up to \$45 per flask.

## Sierra.

**EAST FORK.**—*Mt. Messenger*, August 7: There is quite a little mining excitement going on up the East Fork eight or nine miles above town, in gravel claims, running from the third divide a long distance down the river. It is a large district that has been only partially worked in early days. Some of the miners are, at present, making good wages.

The gravel beds are extensive, running from the ridges down to the banks of the river, and it looks as though there might be a mining camp opened up that will last for a long time.

**SIERRA CITY.**—The cleanup for the month of July at the Young America was \$38,700. The cleanup of the Buttes for the month of July was \$29,500. The cleanup for the month of July at the Cleveland was \$2700. Steelman & Hays found another nice specimen of gold at their claim near Gold Lake, on Tuesday; its weight was 52½ ounces.

**TUNNEL.**—J. Lang has the contract to extend the main tunnel just above Jack Hughes' residence, Downville, to tap the Wheeler ledge that paid so well above, and, though troubled with considerable water, is making good progress. The prospect is fair of a quartz mill being put up there, to infuse new life into Downville.

**CLEANUP.**—The cleanup at the Young America quartz mine, Sierra City, for July, was \$38,700—27½ days' run, with 30 stamps. From the start the ore has averaged \$26 per ton, and last month \$30; and better still, this is only one of the numberless similar valuable ledges, but awaiting the magic wand of capital—"the woods are full of 'em." State Mineralogist Wm. Ireland, Jr., arrived in Downville Wednesday, and will make his headquarters here while investigating the mineralogy of this county. There is no doubt that Sierra is one of the richest quartz counties in the State, and Mr. Ireland's investigations will be of material help to our prospectors. P. A. Lamping, superintendent of the Primrose quartz mine, in Hog canyon, called to see us Wednesday, and stated that his sawmill, to furnish lumber to repair the shaft, is about completed. The pump will soon be at work to drain the mine to the old Primrose chimney that paid so rich in former years. From the bottom of the present tunnel he will have 150 feet of stopping.

**THE MOUNTAIN LEDGE.**—*Sierra Tribune*, August 7: Harry Warner's mine, the Mountain ledge, which has been bonded to Mr. Stoddart, will have extensive operations begun upon it as soon as the latter-named gentleman arrives, which will be in a day or two. This mine lies just south of the Young America, of which it is believed to be an extension. Its outlook is very promising.

**THE PRIMROSE.**—The Primrose Mining Company have purchased the De Long claim and extension from D. P. Stewart. A sawmill has recently been erected and operations will be again resumed.

**THE LADY CANYON GRAVEL MINE.**—The Lady canyon gravel mine, situated in Lady canyon, five miles north of Sierra City, is owned by Chapman & Co., who have recently erected on the claim a dam costing \$500. Considerable pay gravel is supposed to exist at this mine.

**DENNIS & CO.'S CLAIM.**—Dennis & Co., in their claim below Loganville, have discovered a new channel, from which they are taking large quantities of good-paying dirt.

**SIERRA BUTTES.**—The last month's yield of the Sierra Buttes mine amounted to \$29,500.

**A BIG YIELD.**—Canessa & Castagnetti made a cleanup for the season last week, at their claim near Loganville. The yield was \$16,000, and only 12 men are employed at the mine.

**A NUGGET MINE.**—*Sierra Tribune*, August 7: Hayes & Steelman's drift claim seems to be a veritable "nugget mine." Our readers will remember that a chunk of gold worth between \$7000 and \$8000 was found in this claim a few weeks ago, and on Tuesday last a nugget weighing about 52 ounces, and valued at between \$800 and \$900, was discovered at the same place. The cleanup at this mine for the season has amounted so far to about \$21,000, and it is expected that the total yield will increase to between \$1000 and \$2000 more.

**SALINAS AND MERCER CLAIM.**—The Salinas and Mercer claim, owned by Messrs. Mooney, Hutchinson, Freeman and Stevens, lies 2500 feet east of the Florence ledge, in the Keystone mining district, and six miles southwest of Sierra City. Prospecting on the claim was commenced about a year ago, and up to present writing about 600 feet have been prospected. The rock, which has a fair amount of surface gold, averages about \$12.50 per ton. Mining men who have examined this property report it as being an excellent prospects.

## Trinity.

**DEADWOOD.**—*Cor. Shasta Courier*, July 31: Collop & Kearny have bought back for \$500 a half interest in the mine on the south side of Deadwood which they sold a few months ago for \$15 for the whole. They are now retimbering their shaft and are going to sink 30 feet more.

**DREADNOUGHT MINE.**—The mill, one of Huntington's roller quartz, is now doing its regular work in an excellent manner, under the supervision of Engineers Kelly and Richardson; attached to it is a self-feeder, two concentrators and a rock-breaker, all complete in every particular and everything about the machinery running evenly and smoothly. In the mine, where 11 men are employed, they have commenced stopping with good results. A piece of the ore now before me shows free gold, iron pyrites and plenty of galena sulphurets; just the same kind of rock of which a few tons were milled a short time back, and yielded about \$50 to the ton. They have about 75 tons on the dump and are still rolling it out in a lively manner. The capacity of the mill is from eight to ten tons in 24 hours.

## NEVADA.

## Washoe District.

**CONCENTRATORS.**—*Virginia Enterprise*, Aug. 6: Ten stamps of the Con. California and Virginia mill, near the C. and C. shaft, will start up to-day on ore from the mine. Four Frue concentrators will be put to work on the run from these stamps, and if found necessary or advisable more will be added. This is being done by way of practical experiment, and if the results are satisfactory, this method of working the vast amount of low-grade ores known to exist in the mines will be universally adopted by all mining men. Two of these concentrators have been in use for the past four months at the Santiago mill on Carson river, and the result has been so satisfactory that 14 more have been ordered and received, and will be set to work as speedily as possible. The Santiago mill runs on ore from the Crown Point and Belcher mines.

**SAVAGE.**—On the 600 level the main south or

southeast lateral drift has been extended about 35 feet, all in the same fine ore mentioned in last week's report. This drift is now about 225 feet in length from the Gould and Curry south line. Crosscut No. 2 west from it is in 75 feet and shows about 20 feet of very good ore. Crosscut No. 3, which is 54 feet further south, is in 15 feet and also in good ore, showing the ore vein or deposit to be continuous for 150 feet or more and of unknown width. It is the genuine old-time Comstock ore, some of it assaying high in the hundreds, and the active hoisting of it through the Gould and Curry shaft for milling was commenced on Thursday morning.

**HALE AND NORCROSS.**—On the 3100 level, east crosscut No. 1 is out 70 feet, all in vein material, but showing nothing of importance in the way of ore in that direction as yet. Crosscut No. 1, west, is in 18 feet, all the way in quartz, carrying strong mineral indications, and crosscut No. 2, west, is in 30 feet in quartz, and the face in good ore. Crosscut No. 3, west, was started yesterday at a point 70 feet north of the deep winze station, and crosscut No. 2, east, opposite to it, was also started yesterday. Both are in quartz and vein porphyry, with no water to interfere.

**CHOLLAR.**—The only work is on the 3200 level, in the crosscut west from the south lateral drift. This is 35 feet south of the Combination shaft station, and has been advanced westward to the distance of 57 feet, all the way in solid quartz, carrying but little mineral. It was expected that this crosscut would intersect the ore vein found in the west face of the station, and it may yet do so further in. A slight seepage of water comes in at the face of the drift.

**GOULD AND CURRY.**—The north lateral drift 150 feet above the track floor of the 600 level has been extended 49 feet, making a total of 157 feet. Material, quartz and porphyry. A northwest drift has been started at this point from the east side of the upraise winze. This is now in 15 feet in quartz and vein porphyry.

**BEST AND BELCHER.**—On the 600 level west crosscut No. 1 has been advanced 49 feet, making a total of 94 feet, in a vein porphyry and clay formation. The heavy stone bulkhead is being put into the north lateral drift on the 2500 level, and the pumps of the Osbiston shaft hold the water reduced to 20 feet below that level.

**CROWN POINT AND BELCHER.**—All mining work continues suspended until the repairs to the main incline engine at the 1100 level are concluded. This will take two weeks longer. All the machinery had to be hoisted out, the engine foundations cut down, and the machinery will, of course, all have to go down again.

**OPHIR.**—All work in this mine is now confined to the 1300 and 1465 levels, drifting south on both levels from the Ophir shaft. The shaft is also being repaired and put in good working trim in its lower portion. The upper levels are abandoned.

**YELLOW JACKET.**—Daily yield, 140 tons. Operations were interrupted last Tuesday by the breaking of the main spur-wheel, but it was replaced very shortly by a spare one which was fortunately on hand, and work was resumed yesterday as usual.

**CON. CALIFORNIA AND VIRGINIA.**—Daily yield, 400 tons, mill battery samples showing an average of \$14 per ton. The exploration and development drifts on the 1400 and 1650 levels are making the usual good progress.

**SIERRA NEVADA.**—North lateral drift No. 2 on the 520 level was advanced 39 feet, making a total of 427 feet. Formation, vein porphyry with streaks of decomposed quartz.

**KENTUCK.**—The old upper levels continue their regular yield of 40 tons per day of low-grade ore for the Rock Point mill to reduce.

**MEXICAN AND UNION.**—Work in these mines is confined to exploration and development operations on the 700 level.

## Amargosa District.

**A RICH REGION.**—*Cor. Candelaria True Fissure*, July 31: There are but few of your readers who are aware of the existence of the large and rich mining region lying to the south and southeast of Candelaria, in the southwestern portion of Nye county, distant about 120 miles. The country of which I would most particularly speak is on the headwaters of the Amargosa river, and was first discovered in the winter of 1881 by a party from Mammoth City, Mono county, Cal., of which I was one of the number. Little was done upon the prospects, however, until the winter of 1883, at which time a shaft was sunk about 50 feet on one of the claims called the United States, which opened up about nine feet between walls, carrying rich streaks of ore assaying from 100 to 400 ounces to the ton. The next winter the shaft was carried down to about 100 feet, not taking out the whole width of the vein on account of the broken character of the hanging wall. The ore continued and grew more solid, carrying same character of ores, which are somewhat base, similar to some of the ores in your portion of the country. This mine of which I speak is on the extreme southern end of the line belt which extends along and near the base of what is put down in Lieutenant Wheeler's map as the Bare mountains for a distance of about 14 miles in a northwesterly and southeasterly direction. There are about 20 locations made on the belt, all of which show on the surface the same rich character of mineral. Toward the northerly end, however, there are some claims which assay as high as 500 ounces in silver and 60 per cent lead, and some of them show 40 per cent copper and from 200 to 400 ounces of silver with a small quantity of gold. But little work has been done save the necessary assessment work, on account of the poverty of the owners. More work will, however, be done this coming winter. Wood in large quantity can be obtained within 18 miles, with no expensive roads to build. Water is plenty within three to nine miles of the different claims, with good roads. Large quantities of hay can be cut and vegetables raised on the oasis in close proximity, while grain in any quantity can be reasonably purchased at Pahrump and Yount's ranches, some 75 miles to the south. But little prospecting has been done in the surrounding hills, but every evidence points to the fact that a large and rich field awaits the thorough and experienced prospector, and it is, without doubt, a portion of country that will, in the near future, command the attention of men of capital. The main thing that now retards its growth and de-

velopment is the lack of railroad facilities to insure cheap transportation.

#### Columbus District.

**HOLMES.**—Candelaria *True Fissure*, August 7: In the east end of seventh level, we are extracting ore from the old Belle footwall ledge. The ledge is small, but the ore is good and is just like the ore that came from the upper levels during the early working of the property. The stope below the General Thomas stope near the old seventh level is producing well. The average assay from the ore is from \$40 to \$50 per ton. The drift running south to cut the continuation of this ore body has not reached the ledge. We expect to cut it during the present week. The stope below the eastern end of Bob Morris ledge looks well and is producing well. We think this ledge is the same as the Morris ledge, and what we supposed was the east end of the Morris ledge is only a barren spot in the ledge. All of this country is very promising. The stope below east end of eighth level continues to produce well. The ore from this stope is high grade. In the main tenth we are running south to cut the Yankee ledge. The Cross development looks well, and we have the ground open so that we produce a large amount of ore. The Creer stope still produces the usual amount of ore. Mill No. 1 is running on Mount Diablo. No. 2 started on full time this morning on Holmes ore. Everything at mills and mine is in good order and doing good work.

**CANDELARIA W. W. & M. Co.**—The new mill started up last Monday on custom ore, and after running three days resumed crushing Georgene ore.

**TILDEN.**—Notwithstanding the unprecedented depreciation in silver, S. W. Thomas continues to pile rich ore on the Tilden dump.

**MOUNT DIABLO.**—Bullion shipment August 3d, \$10,607.04. In accordance with orders received from the San Francisco office, we have stopped taking out ore and discharged 58 men, and the men now remaining are all engaged in exploratory work. We have stopped shipping ore to the mill and the ore remaining at the mill will be worked up and the mill cleaned up as soon as possible. We have resumed sinking the incline, which is now 45 feet below the eighth level.

#### Esmeralda District.

**AURORA ASSAYS.**—Walker Lake *Bulletin*, Aug. 4: The Esmeralda Con., in addition to working the Humboldt and Juniata, has commenced work on the old Esmeralda. The mill is kept constantly at work and the mines are paying. Tanagerman has resumed operations on the "85," which is opening up rich; the rock is being hauled to the Miners' mill. His claim is now attracting a good deal of attention, and within the last few days has been examined by several prominent mine-owners and operators. The Lord Byron is meeting the most sanguine expectations of its owners. The work on the Antelope is being pushed forward as rapidly as possible with favorable prospects. An accident occurred last Monday afternoon in the "85," which came very near causing the death of a miner named Frank Dorenberg. A rock fell from the roof of the tunnel in which he was at work, cutting his head in several places; the wounds are serious but not necessarily fatal.

#### Pennsylvania District.

**LOOKING WELL.**—Pioche *Record*, Aug. 4: At this district, as in regard to the mines, everything is looking well. The ore in the mine keeps gradually improving in silver and retains its high percentage in gold. The supply of water at the mill is insufficient at the present, owing to the drought, and the mill is not running steadily. Arrangements are being made to bring in another spring.

#### Pioche District.

**AN ACCIDENTAL DISCOVERY.**—Pioche *Record*, Aug. 4: Many are the strange ways in which mines have been discovered, and frequently through mere accident. As a couple of men were walking along the hills last Sunday they happened to see a tarantula come from out a hole near them. In looking for a stick to poke in the hole one of them picked up an old rusty scraper. In prodding the hole from whence the tarantula came they pulled out some dirt that took their attention. It was a sort of yellow-green in color. They cleared away the soft surface dirt, got some of the truck, brought it to town and had it assayed on Monday. It showed 53 ounces in silver. The men worked on the claim the most of the week, and, like all prospectors, they see millions in the near future. The showing is so favorable in Billy Keihler's mine that a couple of miners have agreed to sink it 60 feet deeper, and on the completion of the work they are to have a lease of the mine for sixty days.

#### Silver Peak District.

**HUBERT CONCENTRATORS.**—Candelaria *True Fissure*, Aug. 7: Joseph Hubert, the inventor of the celebrated Hubert concentrator, came in last evening from Silver Peak, where he has been putting up and getting under headway the first one of the machines ever operated in Nevada. When he left, everything was working smoothly. The tailings deposit upon which the concentrator is working contains about 18,000 tons. It is located at the old Blair mills and carries both gold and silver. Mr. Hubert left for San Francisco this morning. He will return in a short time and put up one of his machines at Pine Grove. But little is known in this section of the practical working of the invention, but a number of them have been and are in use in Arizona, where they give universal satisfaction.

#### ALASKA.

**Juneau Alaskan**, July 2: There are about 60 men employed in the placer diggings in the basin at this time, including Indians. There are some new grounds being opened up, and among them one on the west side of Gold creek, along the steep mountain side is yielding well. The Treadwell mill is running full time and force, and while they do not let the public know what they are cleaning up, you may set it down as certain that last month's outcome amounted to more than \$100,000—yes, several thousands more. There are a number of the other ledges on the island now being gotten in shape for further development, and the indications are that there will be one or two other paying mills in operation before long. Among the most promising of

these is that now under the management of Mr. George Nowell, representing Boston capitalists, and that in Mr. N. A. Fuller's charge, owned by parties near home. Mr. A. J. Johnson, representing certain French and California capitalists, has now on the wharf a novelty in the shape of an ore-crusher, which is facetiously called the coffee-mill, on account of its remote resemblance to that article. He has acquired some interests in the ledges of the basin, and proposes to develop them by means of this machine, which he claims can do very effective work. Mr. Johnson is agitating the question of a wagon-road from the town to the basin, and it looks as if the project will soon take definite shape and the work be begun.

#### ARIZONA.

**GLADIATOR.**—*Silver Belt*, Aug. 4: The property known as the Gladiator mine, which forms the north-western boundary of the Globe copper mine, can no longer be classed as a prospect. Recent developments prove the claim to be one of the most valuable in Globe district. A crosscut at the 40-foot level, near the northeast end, shows copper ore for eight feet; the breast is still in solid copper which assays 36 per cent. The Gladiator is owned by W. T. McNelly and A. Bailey of Globe and C. M. Hatch of California, represented by F. C. Hatch.

#### COLORADO.

**ORE.**—Idaho Springs *News*, Aug. 7: The Bald Eagle, operated by Cutler & Co., is shipping large quantities of ore. Dan Doyle has leased his great Eastern lode, Ute Creek, to Pat Pender & Co. A force of men will be put to work at once, and we expect to hear of good returns shortly. Little did we think a few years ago, when the monthly output of this district could be shipped in one car, that a few years would witness such changes. Now it takes hundreds of cars to ship the ore away. This week the sale of the Denhigh mine, discovered and owned by John Protheroe and others, situated near the Jones & Walker lode, Russell district, was completed, Mr. Fred Powell being the purchaser. The consideration named in the deed of transfer was \$20,000. Mr. Powell will work the property. On Tuesday we saw at Allen's works 11 tons of splendid looking ore from the Argo mine. The machinery is now in place, and everything ready for a large and continuous output from this promising property. Mr. Hall makes a splendid manager, and under his skillful and economical charge we hope the Argo will develop into a large and steady producer. The Wallace lode, Ute creek, owned by Robert Turner, Joe Allison and John W. Ward, and worked under lease by Wash Johnson & Co., is showing up well. About three tons sent to the sampler this week netted \$443. Some of the ore runs at the rate of \$235 per ton and some at \$103 per ton.

#### IDAHO.

**WOOD RIVER.**—Ketchum *Bulletin*, July 31: The present mining outlook for this section of Idaho was never more encouraging than at the present time. It is true a few of the mining properties are not showing up as favorably as heretofore, but the great majority of both prospects and mines in all localities in this section are developing into producing properties. The days of booms have gone by, but now the sober, industrious miner goes to work in a systematic way to develop the mineral wealth of the country. To-day the ore output on Wood river is greater than ever. The leasing system is the means by which the country's wealth will be shown up. Experience is a great teacher, and it has taught mining men that there must be perseverance, industry and practical knowledge combined to succeed in profitably operating and handling mining properties. This is now being done. The towns on Wood river are dull, money scarce and trade dull at the present time. This is the condition throughout the United States. The reaction will come surely to Idaho, but how soon is a question. It may be somewhat dull now, but it is only a question of time when Wood river will be one among the best mining sections of the country.

**CARBONATES.**—Ketchum *Bulletin*, July 31: They have struck an eight-inch vein of carbonates in the Black Horse mine. Charley Weaver and H. Delano have taken a lease on the old workings of the Black Horse mine. They are now working their lease and have some good ore in sight. Mike Carey has five men working his lease on the Irving mine, Boyle Mountain. Dead work is now being done, and it is expected a new ore body will be opened up in a few days. Messrs. Greenhow & Rumsey and L. Roberts and Andy Nelson have leased the Maud and May mine on Greenhorn. Louis Roberts went down to see the mine Thursday. He reports some ore being taken out. Sam Bergman has 200 tons of ore on the way over from his Tyrolse mine in Germania Basin, Custer county. It will be sampled at the Ketchum sampler. It averages 150 ounces to the ton. C. B. Marlatt has the contract to do the ore hauling. Jake Lockman, Lou Williams and Dave Jones have taken a lease on the Scott mine from A. Dollarhide & Son, on Smoky. They will have to run several feet of a tunnel before reaching the vein. Lou Williams and Dave Jones are now working the lease. H. L. Dickenson and Sam E. Snow own the Phoenix mine, about four miles from the Star of Hope mine, Lost River mining district, Custer county. Supplies and tools were taken over Thursday by J. H. Fitzgerald. George Mussar and Sam Snow have gone over to do representative work. They expect to remain at the mine about three weeks. A 50-ton capacity concentrator is being built at the Carrie Leonard mine. There are large quantities of concentrating ore in the Smoky section that is now unmarketable, but when the new mill gets to working, all this ore can be profitably handled. Joe Perkins came down from Boyle Mountain Thursday with a load of Irving ore. He informs us that Mike Carey has struck a new body of ore in his Alva mine on Boyle Mountain. Some time ago about \$3000 worth of ore was taken from a pocket in this mine, but the vein was lost. The present vein promises to be permanent, and a good output of fine ore may be expected. Popham brothers have sold their interest in the Star of Hope mine in Lost River mining district to Jos. Pinkham, I. I. Lewis and B. Boree. Mr. Boree is connected with the Philadelphia smelters.

**ANOTHER FIND ON WILLOW CREEK.**—Wood River *Times*, Aug. 7: Zach Hayes, who has a stopping place on Willow creek, a couple of miles from Vanlandingham's, accidentally discovered a good-looking, ore-bearing vein, the other day, while hunting on the divide between Beaver creek and the next creek west. The ore assays \$20 in silver and \$3 in gold. It is free milling. The vein is between four and five feet wide, and the croppings show up for over 600 feet. The Willow Creek country is evidently rich in precious metals, and next summer there will undoubtedly be quite a rush of prospectors to that region.

#### MONTANA.

**GRANITE MOUNTAIN.**—Helena *Independent*, Aug. 5: Captain John W. Plummer, manager of the Granite Mountain mine, registered at the Cosmopolitan yesterday morning. He came in on business at Marysville, where he went yesterday afternoon, and will return to-day and go home in the evening. Mr. Plummer says the Granite output during July has been about the usual amount, and the regular monthly dividend of \$100,000 has just been declared, making \$700,000 which the company has divided since the first of the year, and \$1,300,000 which has been paid in 20 consecutive monthly dividends. During the past week, Capt. Plummer says, the mill has been working on \$200 ore. He is constantly sacking very rich ore—ore worth \$1 per pound and even as high as \$5000 per ton. This ore is so very rich that it cannot be worked to advantage by ordinary plants, and it is not at present known where it will be shipped. He is shipping smelter ore from one ledge of the company's property to Omaha. Some idea of the magnitude of the Granite property may be gained when it is stated that beside great bodies of ore in the stopes, there are 1700 feet of tunnels and levels running along ore chutes that have not been touched except to crosscut them at intervals to ascertain their width, which is 10 to 14 feet and more. The mine is now in such condition that 100 tons per day could be taken out if necessary. The new mill is being built just as rapidly as possible, as there is lots of work for it to do.

**FROM THE YELLOWSTONE COUNTRY.**—James Gourley, of Bozeman, interviewed by the *Independent*, said: I regard Cooke City as the coming camp of the country. It has the carbonate character of Leadville. There have been some great developments there recently. The Great Republic Company is taking out eight tons per day, which averages \$250 in bullion. The company ships its ore to Cinnabar and is paying \$1000 per week for wagon transportation alone. The Ashe mine, owned by Jackson and others, is showing fine development, the mining corps having struck a rich vein of carbonate carrying silver. In the Shoo Fly a similar vein has been struck. This mine is owned by Gassett & Co. In fact, all of the work in the camp is making a splendid showing, when it is considered that the camp has no railroad and no capital to operate on. The work is done by the men who own the mines, as a rule. At Emigrant Gulch there are also big developments, both in quartz and placers. Conrad & Co. have struck a rich gold lead. They are running a tunnel about 180 feet, by which they have struck a six-foot vein. These men have been years on this lead, and have at last struck it. They are getting good results from an astrata that they are working. The placers are also panning out well, especially those of Gliddin & Co. and Flesher & Co. At Bear they are running the hydraulic works for all they are worth, and are bound to have big results in the course of time, as the mines are rich. As to quartz, they are making great progress in Bear Gulch. If they had machinery or easier railroad access, you would get some big results from Bear.

**ANOTHER STRIKE.**—Butte *Miner*, August 7: Yesterday Col. Desreivres, of Jefferson county, came into Butte and brought with him rich samples of ore from a prospect recently located by himself and his partner, Mr. McBee. The assay was made by Mr. M. E. Mayer, and shows 399.73 in silver and 15 per cent in lead. The ore is of chlorides and sulphurets and the gentlemen are satisfied they have struck a veritable bonanza. The location is in Soap gulch, about three miles from Meaderville, and in a county that has been prospected for years.

#### OREGON.

**MILL SOLD.**—Bedrock *Democrat*, Aug. 4: Since Laurence & Starr of Prairie City have sold the Keystone mine and mill on Dixie creek, there is considerable quartz excitement there. There are a number of other valuable ledges in that vicinity which are more extensive and prospect better on the surface than the one sold. This sale has given an impetus to the mining interests of that section which promise to result in a substantial growth and improvement in mining matters. The purchasers of the Keystone will discard the old mill and replace it with one capable of crushing not only their own quartz, but also all that will be brought to them from other ledges. There is talk of laying out a town near the mines and a great boom is expected. We understand that Laurence & Starr will expend the money paid them in developing other ledges they own a short distance from the Keystone.

**PINE CREEK.**—Men of the "I-told-you-so" class are now standing around with this favorite expression on their tongue's end whenever anything is said about Pine Creek. "I told you there would be no boom," said one of them to the *Sage Brush* reporter yesterday. That was the worst he could say about the camp, and that was nothing against it. We do not deny that better times were expected for this season in that section, but it is only a question of time when that will be one of the richest camps on the coast. There are no rich and extensive placer mines in that section from which to obtain rich results in a short time. The ore is refractory, requiring a large amount of expensive machinery—such as it requires capital to purchase. Such being the case, the development of the country is necessarily slow, and a poor man has but little chance to continue with his development for any length of time, as he has to make preparations for the winter. With a few exceptions the ledges are owned by men without means who must await the action of the Louisville or other companies before anything can be realized from their work. The great rush in all mining excitements is composed largely of poor men;

but what inducements does Pine Creek offer to these now? To be over-crowded with this class now would be a detriment to the camp. The poor man's day in Pine Creek is approaching; when there are mills and machinery, roasters and smelters, there will be plenty of employment, and the "I-told-you-so" men will be changing the same words to a different tune. Pine Creek is no failure, but on the contrary a country that will be noted even beyond the waters when the proper time comes—and that time is fast approaching.

**PLACERS AND QUARTZ.**—Jacksonville *Times*, Aug. 7: Many of the placer miners are already getting ready for winter. Considerable prospecting is still going on in Jackson and Josephine counties. A small quartz mill is being put up at Wm. Griffin's quartz ledge in Josephine county by Portland parties. B. A. Knott is busily engaged in taking rock from his ledge, and expects some one to put up a mill soon to crush it. He has a good mine. The quartz mines of the county are receiving more attention than ever, and we expect to see them prove valuable in the near future. Keaton, Klippel & Co. are busily engaged in opening their new mines on Applegate, and will have them in shipshape by the time winter comes. Grob & Braendel will soon resume work on their quartz ledge, and intend to have a considerable quantity crushed by Baumle, Klippel & Co.'s new mill. The quartz mill formerly at Medford, which has been removed to Wagner creek, is now in running order and pounding quartz from the Hope ledge. A number of prospectors are arriving from Idaho and other mining regions, several of whom propose to do considerable work in Jackson and Josephine counties. The past season has been much better than any of the three previous ones. C. C. Beekman, of this place, has bought a large quantity of gold-dust during the past few months. J. N. Casteel is making excellent progress with the tunnels of the Jacksonville Milling and Mining Co. and C. C. Beekman. He has almost finished his contract with the former. Messrs. Rush and Taylor, of Eugene City, are in this section looking after their mining interests. They have discovered and are opening a well-defined quartz ledge in Jacksonville district. A. W. Sturgis closed a successful run at his placer mines on Forest creek not long ago. He will have hydraulic pipe and a giant there next season, and has already given his order for the same. The Wagner Creek Mining Co., which has a Huntington mill crushing quartz from the Pilgrim ledge, made a cleanup lately, the result of which is unknown. The mill is being run day and night. Saltmarsh & Co., of Sterlingville, have about completed cleaning up. They picked up a nugget worth \$16, some time since, which denotes the existence of a rich ledge in that vicinity, as it contained considerable quartz. Work has been suspended temporarily at the mill at work on the ore from the Swinden ledge. It is said that L. D. Brown will soon put up better machinery which has more capacity, when operations will be resumed with renewed energy. There is no doubt but what the ledge will pay well and regularly, if worked properly. Several men are engaged in putting up the wood-work for Baumle, Klippel & Co.'s quartz mill in Shively gulch, which will be completed before long. Mr. Klippel has gone to San Francisco for more machinery, and as soon as it arrives no time will be lost in putting it in running order. This will prove of great benefit to the whole district, as it will be conducted on legitimate business principles.

#### UTAH.

**REVIEW.**—Salt Lake *Tribune*, Aug. 6: The bullion receipts in this city for the past seven months were as follows:

January.....	\$ 328,852 66
February.....	456,024 93
March.....	469,722 63
April.....	519,666 08
May.....	387,891 49
June.....	527,036 97
July.....	585,644 38
Total.....	\$3,274,888 24

This excludes all receipts of ore, and there are also undoubtedly some of the smaller producers not included in full. The output of the Ontario for July was \$80,894.93 in fine ounces, and \$60,226.01 from ore sales, an approximate total of \$141,120.97. This brings the Ontario product of the year up to \$1,027,839.39, not being exact owing to fluctuations in silver. Out of this have been paid seven monthly dividends of \$75,000 each, or \$525,000 in all. The Daly product for July was 45 bars of bullion, 61,809.93 fine ounces, and \$16,105.80 from ore sales, an approximate total of \$77,915.73; a total output for seven months of \$389,644.78. The shipments of the metals out from Salt Lake for the week ending Saturday, July 31st, inclusive, were 70 cars, 1,825,167 lbs. The receipts in this city for the week ending August 4th, inclusive, were—bullion, \$130,844.77; ore, \$77,403.32; total, \$208,248.09. The previous week the receipts were \$127,372.51, of which \$81,280.59 was bullion, and \$46,091.92 was ore. The Daly product of the week was 18,014.14 ounces of fine bullion, and ore sales \$7468.59, a total of \$25,482.71 for the month, approximately. Receipts of fine bars for the week were \$82,508; of base bullion, \$15,600. The Hanauer smelter shut down for its annual repairs and cleanup on the 1st. Its product for the week, prior to that date, was \$12,990; the Germania product was eight cars, \$14,936 77; for the week; that of the Pascoe \$1505. The Stormont sent up \$3305 in silver on the 29th.

**PARK NOTES.**—*Record*, Aug. 7: Supt. Jones, of the Sampson, has made some extensive improvements in the Sampson tunnel, and since air connections have been made the mine can be worked to good advantage. The ore shipments will assume large proportions very shortly, and the Sampson will undoubtedly be put on a good footing.

**ORE AND BULLION SHIPMENTS.**—The Mackintosh sampler received for the past week 440,040 pounds of Ontario ore, 111,620 pounds of Daly and 14,640 pounds of Sampson ore. During the week the Crescent shipped 285,000 pounds of concentrates and 190,000 pounds of first-class ore. The Ontario bullion shipment for the week aggregated 66 bars, containing 37,964.89 fine ounces of silver. The Daly bullion product from the Marsac mill for the week was seven bars, containing 7560 fine ounces of silver.

## A Colusa County Residence.

As our State is full of visitors, going about to see some new thing, we have thought we might entertain them as well as our old readers by giving a view and description of one of the most remarkable residence buildings in California. It is the home of L. F. Moulton, and is situated near Colusa. The general exterior aspect of the building, from one point of view, may be gained from the engraving on this page, which is made from a photograph. Perhaps the first feature which strikes the beholder is the height of the structure. A person standing upon the tower which crowns the residence has his eye about 75 feet from the ground, and this altitude gives a grand view of the Sacramento valley and river to the south, the Coast Range to the west, the Sierras to the east, and the eternal snows upon Mt. Lassen and Mt. Shasta to the north.

Mr. Moulton's residence contains many novel features, in fact, nearly everything about is novel and characteristic. Take first the portion that first strikes the observer by its bold elevation. The engraving shows that the central portion rises four full stories, and overtowers the other parts. This is, in fact, the tankhouse, for instead of erecting his tank-house apart from his residence, as is commonly done, Mr. Moulton has made his tank-house a central idea in his house planning, but has made such good use of the space and so elegantly fitted it up that no one would discover any likeness to its progenitor the tank-house. The interior of the tower is used for an elevator and around it is the stairway. There is also space for an observatory where a telescope may be arranged.

At the very top of the tower is a lookout which forms the roof or deck over the main tank holding 1500 gallons, situated 65 feet above the ground. This tank has a supply pipe of galvanized iron two and a half inches in diameter, which pours into it from above, and another similar pipe from the bottom for distributing the water. Connected with this are three-inch pipes which carry water for fire purposes to about 25 buildings situated within a radius of half a mile. From the tank there are also a 2½-inch and a 2-inch pipe leading to hydrants at all necessary places, for the purpose of extinguishing fires, watering stock, irrigation, etc. The water to supply the main tank is obtained in this way: There are two Garret pumps, one on each end of a 2½-inch iron shaft, 80 feet long. This shaft is supported on a frame and is run by steam or horse power as desired. It is so arranged that either or both pumps can be used at will.

Under each of the pumps are wells with pipes running directly into them, and pumps are also connected with four other bored wells, in different directions. In this way they draw upon a large area of water space below the surface, instead of one large well as is usual. Mr. Moulton finds that bored wells cost less and are not liable to get out of order.

Aside from the large tank surmounting the tower there is another of 500 gallons capacity, which receives the rain-water from the house-roof and is the head of the system of water supply for domestic use, in wash-bowls and bath-tubs, as there is hot and cold water throughout the different stories of the house. There is also a system for flooding the house-roof, etc., with water in case of fire and means for drawing off quickly any water thus set free,

which must be seen to be appreciated, as their plan is very ingenious and working effective.

Another notable feature of the residence is its chimney system, which is quite as remarkable in its way as the water system. The chimney is a large structure to the center of the

mantels. This chimney runs up through three grand rooms, one above the other, and each 22½ by 32 feet in size; other rooms, arranged to suit convenience, communicate with the main rooms. On the ground floor, as shown in the plan, the large room 22½ by 32 feet opens by

nomical observatories. The telescope support has eight arches, supported by columns, through the center of which runs 15-inch pipes, and these will be slanted up and out of the way above, so as to reach open air and unobstructed draft.

We have not space to comment at greater length upon Mr. Moulton's structure. A study of the engravings will show the reader many points not described. His house is located on a farm comprising 9000 acres of high grain land and 9000 acres more, which are partly subject to overflow; but the lowest is said to be good hay land, and also has fruit trees and vines that have lived through the worst overflow of many years. Mr. Moulton is now preparing to set out 100,000 young prune and pear trees, having a large lot of imported French stocks, which he will bud this summer, besides other hardy stocks now growing in the nursery. The farm has about 30 miles of fencing, inclosing all but the grain land.

We have heard that the ranch has produced as high as 120,000 bushels of wheat in one season, besides other products. There are now 200 acres of orchard and vineyard, just coming into bearing. An irrigation canal is projected from Chico creek to the land, which, it is thought, would supply water to irrigate the whole of it.

Colusa county, situated in the center of the great Sacramento valley, is now demonstrating its fitness for a great extension of its list of products, as it is found that its soil and climate are adapted to many fruits and other desirable growths, which will give the region wide fame and tend to the progress of the county in wealth and population.

RESIDENCE OF L. F. MOULTON, COLUSA, CAL.

house, as may be seen in the ground plan, and the top of it is located just back of the tower, in the prospective view. The chimney is 50

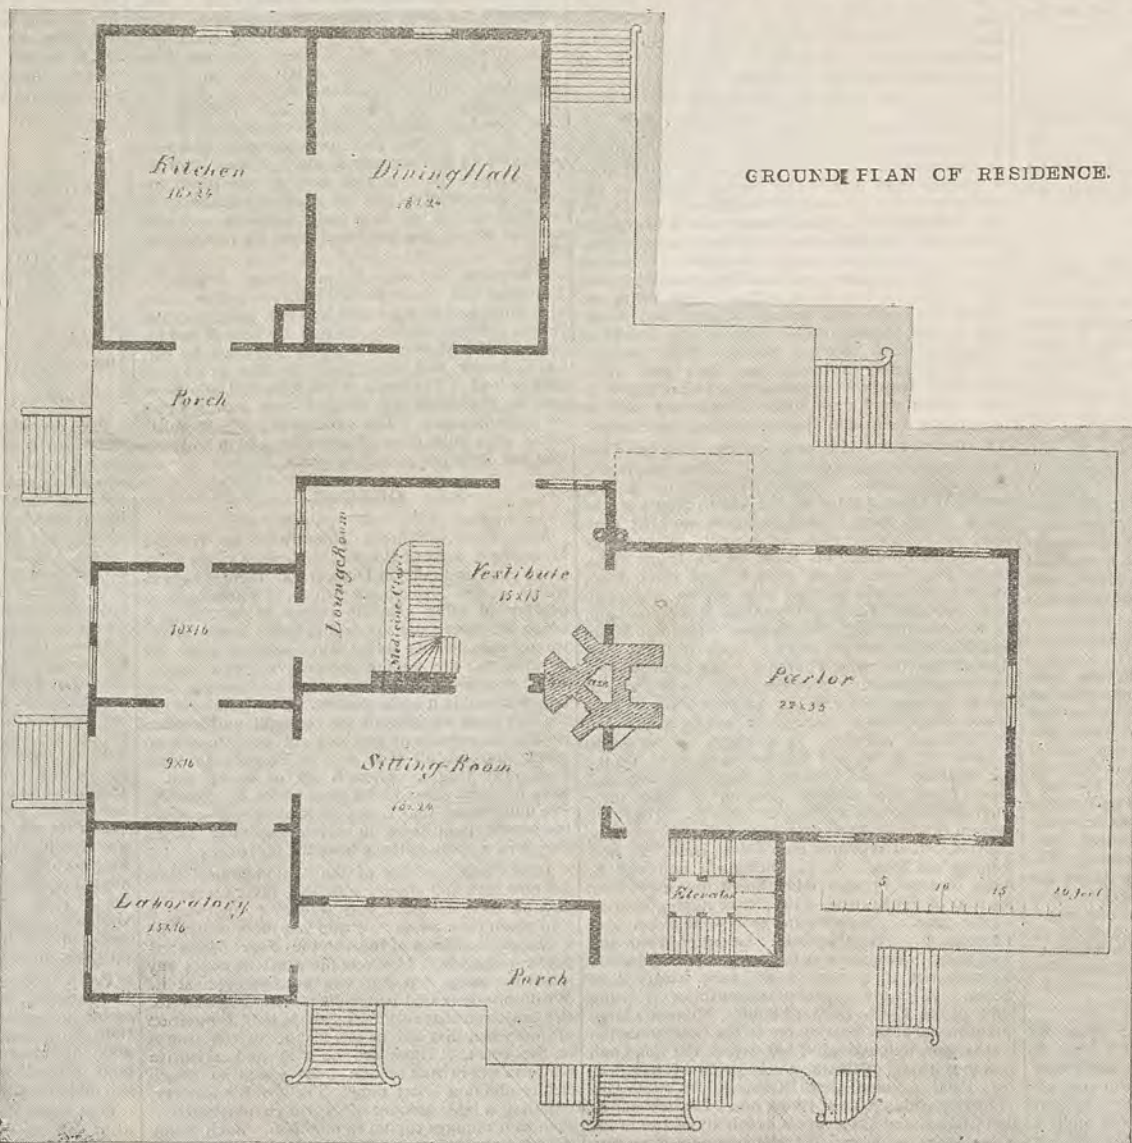

folding and over-head rolling doors into other rooms to the west, which, by double doors, open into rooms still farther west, and these by

IRON IN THE BLACK HILLS.—NEW YORK, Aug. 5.—At the Iron and Metal Exchange there is some conversation concerning the inter-

esting experiments just now being made in this city with quantities of tin ore that is now found in great abundance in the Black hills, D. T. The tin concentrates are said to be of fine quality. Considering the fact that we import some \$6,000,000 worth of pig tin annually, the domestic production is watched with great interest by the metal trade. A company of New York capitalists has been formed to mine the ore, and some of the more enthusiastic of these declare that Dakota will shortly be able to furnish the United States with tin, so that we need not import a single dollar's worth.

By the recent order of the Interior Department, saw mills in Alaska are not permitted to cut logs and manufacture the same into lumber, except for the personal use of the proprietors of said mills. The order is based on the fact that there are no land laws in that Territory, and no person can acquire ownership to real property. The only persons who have title to real estate are a few Russians who owned land in Sitka at the time of the transfer of the Territory to the United States.

THE proposition of pumping out the submerged mines of Gold Hill is a favored subject for consideration, and overtures have been made to that end, but the party holding the key to the situation is unwilling to consent. It is a movement which most certainly should be made before long, and one that would find good favor with the general stock-dealing public. Some very valuable prospects had to be abandoned when the overpowering flood of hot water took possession of the lower levels of all the Gold Hill mines,

GROUND PLAN OF RESIDENCE.

feet high and 10 feet in diameter at the top; upon which are now placed the pipes from the several flues, as shown in the picture.

The chimney has a hollow center, into which each fireplace discharges its ashes, which may be removed at pleasure from below. The fireplaces are furnished with the choicest onyx

double doors again communicate with the surrounding lawns and gardens in which are rows of orange, citron, lemon, lime and other choice trees which flourish in our mild climate.

It is Mr. Moulton's design to surmount his great chimney with an observatory with revolving dome, of the construction usual in astro-

**THE FEATHER RIVER TURNED.**—In conversation with ex-county Surveyor McGann, last evening, regarding the Big Bend tunnel, and its reported failure to convey all the water of Feather river, we learned that the water is all through at last. Mr. McGann received word last evening to the effect that the river had been effectually turned aside from its course, and that its bed is bare. The reason the tunnel failed at first to take all the water was that the dam that was built was not high enough, and the mouth of the tunnel was not large enough. The dam was only six feet high. The mouth of the tunnel was obstructed by several columns, and thus some of the water was forced back and flowed over the dam. But the dam has been raised in height to overcome the resistance offered by the columns, and the increased pressure has forced all the river's contents through the tunnel, leaving the bed bare for mining purposes. The only change that will have to be made will be the widening of the mouth of the tunnel. Its capacity is fully sufficient to hold all the water when it is once forced in.—*Chico Enterprise*.

**OCCURRENCE OF ALABANDITE.**—A mineral having the physical properties of alabandite, and, according to tests made by Mr. Robert Neuman, giving the reactions for that mineral, occurs in considerable quantity in the Queen of the West mine, in Horsehoe, Summit county. Should subsequent investigation prove the mineral to be alabandite, it will be its first observed occurrence in the United States. The mineral is of iron-black color and metallic luster, with a dark-green powder. It has a cubic cleavage, and when crystallized occurs in cubes and octahedrons. The theoretical composition of the mineral is: Sulphur, 36.7; manganese, 63.3. The Queen of the West mineral carries 30 ounces in silver to the ton. We are under obligations to Superintendent Foote for a specimen of the mineral. Alabandite has heretofore been found in the gold mines of Nagyag, Kapnik and Offenbanya, in Transylvania; at Gersdorf, near Freiberg; in Mexico, at the mine Preciosa, in Puebla, and a few years since it was found in Peru.—*Georgetown (Col.) Courier*.

**THE OIL WELL.**—The boring of the coal-oil well at Sargent's tar springs is in progress. The auger was down 104 feet from the surface on Saturday last, and more headway has been made the present week. Oil floats on the surface of the pulverized rock, sand and gravel of the strata through which the drill passes on its way to its source. Mr. Taylor considers the prospect more favorable than it has appeared to borers in places where the flow exists in paying quantities. He expects soon to be able to telegraph the cheering intelligence that he has struck oil, the supply of which will add to the business of the valley. As in Santa Barbara, it is probable that success might reward the oil men by tunneling the hill.—*Gilroy Advocate*.

**IF EVERY SUPERINTENDENT** of a mine would be given absolute power to push work on the property over which he superintends, and in what manner and to any extent he judges best, and is not subject to the orders of a Board of Directors living thousands of miles away, more of our mines, we believe, would pay larger, and give more satisfactory results. A practical mining man, who is well acquainted with the workings of a mine, is better able to judge as to requirements in the way of development, etc., than theoretical miners who know nothing about the practical operation of a property.

**THE NAPA & LAKE RAILROAD.**—Two hundred and fifty men are now working on the Napa & Lake railroad, and it is said there will be 500 working by Saturday. The road starts from Rutherford, and will go to Lower Lake, a distance of 45 miles; but it is intended to push right on to Lakeport. From Rutherford the railroad will connect with the Napa road at a point about 14 miles above Napa. The matter has been kept very quiet, but the company evidently mean business right away. John T. Davis is president and S. M. Holmes the treasurer. Both are Boston men.—*Sacramento Bee*.

**PNEUMATIC TUBE MINING.**—A dispatch from Oroville, Butte county, dated Aug. 4th, says: The mining company that has been operating the pneumatic tube at this place struck very rich gravel this morning. The company is very jubilant over their prospect, and will put in at least two more tubes. By the pneumatic process, ground can be worked that cannot be by any other process. The gravel deposit is in the bed of Feather river, and about 40 feet below the surface of the water.

**THE Redding Free Press** says: Clarence E. Foster, the great Tennessee colony organizer, has been visiting Shasta and Modoc counties looking for a location for a negro colony from the South. He found what he wanted in our northern valleys, and a colony will soon be on its way here. The object is to bring the negroes here to raise cotton.

**THE** fine and costly steel wire cable of the Yellow Jacket new shaft, eight inches in width and 3500 feet long, is being split in the middle for its entire length. This is in order to make two cables four inches wide, needed for use in the old shaft workings. The splitting is being done by means of coldchisels and hammers—a slow but very sure process.

## USEFUL INFORMATION.

### The Value of Brick-dust.

The clays from which bricks are burned are composed principally of silicate of aluminium, with varying proportions of other silicates (iron, lime and magnesia being present as bases). When burned, these clays are in just the condition of that which is employed in the manufacture of Portland and other artificial cements, and in the presence of moisture will promptly unite to form with lime the double silicate, the formation of which is the cause of the "setting" of such cements. The use of brick-dust as an ingredient of cements is by no means unknown, but in some localities is a well-established practice; and such cements figure as a regular article of commerce. Trautwine says on the subject: "Brick-dust or burnt clay improves common mortar and makes it hydraulic." Very positive testimony in its favor, however, is given by Mr. F. B. Miles, a well-known manufacturer of Philadelphia. His remarks on this subject are so interesting that we give them in full. Mr. Miles says: "It may not be generally known among builders in this country, that in the Spanish dominions, ordinary brick-dust, made from hard-burned, finely-pulverized bricks, and mixed with common lime and sand, is universally and successfully employed as a substitute for hydraulic cement. During an engineering experience of six years in Cuba, I had ample opportunity for testing its merits, and found it in all respects superior to the best Rosendale hydraulic cement for culverts, drains, tanks or cisterns, and even for roofs, whether for setting flat tiles or for making the usual tropical, concrete, flat roof. It is regularly known there as an article of commerce, sold in barrels by all dealers in such articles, at the same price as cement. The proportions used in general practice are one of brick-dust and one of lime to two of sand, mixed together dry, and tempered with water in the usual way. A greater or less quantity of the brick-dust is sometimes employed when considered desirable." Mr. Miles goes on to say that he does not know whether this composition has ever been tried in this country, or whether it would retain its virtues when subjected to the action of frost. It could undoubtedly be produced at less cost, he adds, than cement; and by the addition of pulverizing mills to our brickyards, to utilize the waste and broken bricks, it might afford a profitable return to enterprising manufacturers, or others who might interest themselves in the product. Trautwine adds to the above the statement that brick-dust cement is used considerably in France. In an experiment to test the strength of this product, he found that a block of the same, one-half inch in thickness, without sand, and after an immersion in water for four months, bore, without crushing, crumbling or splitting, a pressure of 1500 pounds per square inch. With regard to the doubt expressed by Mr. Miles as to the ability of brick-dust cement to withstand the action of frost, we see no reason why it should not stand it as well as other hydraulic cements, with which it is substantially identical in composition.—*Manufacturer and Builder*.

**HOW OATMEAL IS MADE.**—The first operation in the manufacture of the meal is the removing from the oats all the chaff, small oats and foreign seeds of whatever kind, for if any of these remain the quality of the meal is much injured. Black oats, if even of good quality, give a bad appearance to the manufactured meal, as it reappears in the form of black particles, which to the tidy housewife appears to be something more uncleanly. After the oats have been properly cleaned by sifting, they are subjected to the process of drying. This is accomplished in dry kilns, with special apparatus constructed for the purpose. This operation requires some care to prevent the oats from burning. As soon as sufficiently dry they are removed from the kilns while still very hot and stored in such a way as to have them retain their heat; after thus remaining three or four days, they are ready for the shelling operation. This shelling is accomplished by passing the oats through mill-stones of a special pattern. The product that comes from the stones is groats, or the whole kernels, dust, seeds, etc., and these must be separated. By means of combination of sieves and fans the groats are separated from the other material, and are then ready for grinding. For extra quality meal the groats may be shelled and also passed through a brushing machine. The grinding of them must not be long delayed, as a few weeks' exposure renders them unfit for milling. In grinding the groats the great aim is to avoid pulverization and to have the granules cut square and of uniform size. Oatmeal is generally denominated by the cut—as pin-head cut, rough cut, medium cut—although these terms have different meanings in different districts. After the grinding the meal is passed through sieves and the siftings graded according to size.

**BAND AND CIRCULAR SAWS.**—A practical correspondent of the *Mechanical News* writes, in regard to the comparative utility of band and circular saws, as follows: "The reason why band-saws are not run as fast as circulars is because it is not practicable. The limit of speed at which they can be run and do their work properly has been fixed by practice. I do not think a band-saw would cut 1000 feet of lumber

in an hour. As the band-saw is thinner than the circular, I should say, on general principles, that it would take less power, cutting at the same rate; and that a band-saw is considerably more difficult to set up and run than a circular saw. That has been my experience, and I think it will be confirmed by others."

**WHAT CAUSES VARNISH TO PIT AND ENAMEL.**—A REMEDY SUGGESTED.—There are several reasons why varnish will pit and enamel. The pitting comes first and is of most importance, because it occasions more trouble and expense than the other, and requires to be washed off entirely, while the other can be rubbed out and revarnished. The most generally accepted reason for pitting is that the varnish is too green or new from the vats to be placed on the market, although there are some varnishes which will pit no matter what age it has, or under what circumstances it is used. Sometimes the very best that can be got will go too. To take up all the reasons would occupy too much time and space, so we will only treat of a few. A damp, chilly room, a draught of cold air blowing in on a panel before it has thoroughly set; a current of electricity running through the air, caused by a thunder-storm. To counteract those influences is simply to avoid them. See that your room is thoroughly dried and ventilated before varnishing, and also see that it is kept so. Take your job out of the current, and do not varnish if a storm is coming or expected to come. About enameling: That can be caused by an overheated room or a heavy, foul atmosphere, or it can be caused by the under coats not being thoroughly dry, or sweating out under the finishing coats. Regulate your room to about 60 or 70 degrees. If there is any heavy, foul air, get it all out, and above all, do not varnish until your under coat is dried out of all possibility of sweating.

**THE NOMENCLATURE OF CARRIAGES.**—Fifty years ago the names of the different kinds of carriages, wagons, etc. in use were few and easily remembered; but at the present day we are overwhelmed with a multitude of fancy names used to designate the particular productions of various ingenious houses engaged in this class of industry. As to the wisdom of this system of multifarious nomenclature, there may be differences of opinion.

## GOOD HEALTH.

### What Science Says.

**The Wonderful Mechanism of the Human System.**

In the editorial columns of the *New York Analyst* H. Lassing, M. D., editor, writes the following beautiful description of the laboratories of the human system. We think we have never read a finer or more trustworthy one:

"Man is the greatest of all chemical laboratories. Magnify the smallest cell of the body and what a factory is spread before the eyes. Countless chambers in which are globes of air, masses of solid matter, globules of dying liquid; a flash comes and the whole is consumed and needful heat is carried into every part of the system. Electrical forces also generate and are conveyed to the brain, the muscles and the various nerve centers.

"In another set of a million chambers we see various classes and vapors. By chemical action these are changed and purified in the lungs and the skin. The blood, we often say, is a great living river. In its current are masses which the air in the lungs did not affect; blocks of chalk, slabs of tartar, pieces of bone-ash, strings of albumen, drops of molasses and lines of alcohol. How are these waste masses disposed of? Begin where you will in this great stream, you must come to the purifying places of the system. Here is all activity and an invisible force reaches out into the stream, seizes and carries this mass of waste into vast trenches, thence into a smaller reservoir, and finally into a larger reservoir, which regularly discharges its contents.

"This separation of lime, uric acid and other waste material from the blood without robbing it of a particle of the life fluid, passes human comprehension. In health, this blood-purifying process is carried on without our knowledge. The organs in which it is done are faithful servants whose work is silent as long as health remains.

"People strangely wait until pain strikes a nerve before they will realize that they have any trouble. They do not know that pain concerns chiefly the exterior, not the interior, of the body. A certain set of nerves connect these blood-purifying organs with the brain. They may not gnaw and bite as does the toothache or a scratch, but they regularly, silently report. When these organs are failing these nerves indicate it by drawing the blood from the face and cheek, leaving the lip and eye blanched, by sending uric acid poison into the smallest veins, the skin then becoming gray, yellow or brown. They also prevent the purification of the blood in the lungs and cause pulmonary difficulties, weariness and pain. Who enjoys perfect health, especially in this land where we burn the candle in one mass? The athlete breaks down in the race; the editor falls at his desk; the merchant succumbs in his counting-room. These events should not have been unexpected, for nature long ago hung out her 'lantern of alarm.' When the 'accident' finally comes, its fatal

effect is seen in a hundred forms—either as congestion, chronic weakness, as wrong action, as variable appetite, as head troubles, as palpitation and irregularities of the heart, as premature decay, as dryness and harshness of the skin, causing the hair to drop out or turn gray; as apoplexy, as paralysis; as general debility, blood-poisoning, etc.

"Put no faith, then, in the wisacre who says there is no danger as long as there is no pain. Put no faith in the physician, whoever he may be, who says it is a mere cold, or a slight indisposition. He knows little, if any, more than you do about it. He can neither see nor examine these organs, and depends entirely upon experimental tests, that you can make as well as he.

"If the output is discolored or muddy, if it contains albumen, lymph, crystals, sweet or morbid matter, is red with escaped blood, or roily with gravel, mucus and froth, something is wrong, and disease and death are not far away.

"These organs which we have described thus at length, because they are really the most important ones in the human system, the ones in which a large majority of human ailments originate and are sustained, are the kidneys. They have not been much discussed in public, because it is conceded that the profession has little known power over them. What is wanted for such organs is a simple medicine, which can do no harm to the most delicate, but must be of the greatest benefit to the afflicted."

### Alcohol and the Blood Circulation.

In chills or in cases of sudden cold, the blood fails to reach the surface and produce or keep up the needed external warmth. If, at such times, alcohol be taken into the stomach, it at once increases the action of the heart and arteries about one-fifth, thus driving, with an unnatural force, the blood to the surface, and producing there the needed glow of warmth.

But, under the same law of cause and effect, if we make an habitual use of alcohol in any of its numerous forms, we unnecessarily increase the circulation, and by frequent potations keep up a flow of blood to the surface faster than the veins can carry it back. Hence, the countless capillaries, whose minuteness makes them invisible under ordinary conditions, soon become distended with impure blood, and are kept in a state of permanent congestion. This impure blood will soon give rise to pimples and blotches, especially upon the face and nose. These are the "toddly blossoms" which are so disgustingly prominent on the face and nose of the hard drinker. If the pimples do not appear, a permanent and noted redness shows itself, as an emblazoned signal, proclaiming to every visitor the tipping habit of the person. The same action of the heart, and in the same manner, produces headache, a coated tongue, an impaired appetite, disturbed sleep, etc. All these things should be taken as notes of warning that the whole system is diseased, and is fast being prepared for a drunkard's grave. The *Medical Reporter*, in referring to the same matter, says:

"It is a medical fact that as the influence of alcohol reddens the dram-drinker's nose, and changes its appearance, so it reddens and changes the appearance of every organ of the body; and as the nose thus affected is not in a natural and healthy condition, so every organ of his body is changed from a natural and healthy condition to an unnatural and diseased condition; and as the skin of the nose takes on unhealthy action, so the substance and coverings of the internal organs take on diseased action, which results in the full development of incurable diseases, such as insanity, diseases of the heart, Bright's disease of the kidneys, hobnail liver, and slow inflammation of the stomach. All these diseases exist at the same time in the dram-drinker, but the organ most diseased is apt to take the lead in the morbid action."

"**WORRIED TO DEATH**" was the announcement that conveyed news of the suicide of a business man in Oakland last week. The words sound like the tolling of a bell. The intensity of business life is caused by the rapid facilities which modern progress has furnished. The old way of waiting for ships to come in had in it leisure. The new way, with every nation in the world connected by telegraph wires and cables, which join all commercial centers together, has put a speed into business to which business men have not yet adjusted themselves. It used to be 6000 miles from San Francisco to London. Now the distance to London is that between your counting-room and the nearest telegraph office, or, to be more exact, it is the few feet between your chair and the electric button you touch to call a messenger boy. Out of this condition of affairs which puts San Francisco and Hongkong nearer to each other than this city and Sacramento used to be, has come into business an increase of contacts, a multiplication of operations, and hence of risks, which would have appalled our fathers. But let no man decry this addition to the facilities of trade, for it has brought more genuinely great men into commerce than ever before. Under the old system a few men flourished, but they can be easily recalled. Jacob Barker and John Jacob Astor in New York, Girard in Philadelphia, and Peter Pan-ueil in Boston and the Winans family in Baltimore, gathered significant fortunes, but who can recollect the names of other cotemporary princes in trade?

#### SAN FRANCISCO:

Saturday Morning, Aug. 14, 1886.

#### TABLE OF CONTENTS.

ILLUSTRATIONS.—Lead "Steam Pump"—(Injector); Plunger Jigs for Iron Ore Concentration, 97. Lava Covered "Old Channels," Showing Contour Line of Surface; Profile Line of Cross Section, 105. The San Francisco Tool Company's Siphon Centrifugal Pump, 107.

EDITORIALS.—Concentration of Iron Ores, 97. Mining Profits; Foundry Notes; A New Mining School; San Diego Mines; Silver and Gold, 104.

CORRESPONDENCE.—Idaho Mines; Mining on the Lower Klamath; Quartz Grinders Again; Washington Territory Mines, 98.

MECHANICAL PROGRESS.—Progress in Saw Manufacturing; Sketching for Mechanics; A Gigantic Steel Forging; Wire-painting Machine; Lubrication of Steam Engines; Boiler Notes; Importance of Thin-blade Saws; To Produce a Red Stain on Wood, 99.

SCIENTIFIC PROGRESS.—Science in America; History of an Ancient Cyclone; Earthquake Waves; Earthquakes and Other Earth Movements; After Sunset Glows; Modern Cave Dwellings, 99.

USEFUL INFORMATION.—The Value of Brick-dust; How Oatmeal is Made; Band and Circular Saws; What Causes Varnish to Pit and Enamel; The Nomenclature of Carriages, 103.

GOOD HEALTH.—What Science Says; Alcohol and the Blood Circulation; "Worried to Death," 103.

MISCELLANEOUS.—Defining Coperny Bullion Produced by Amalgamating Tailings, 97. Drift Mining in California, 105. Siphon Action of Discharge Pumps, 106. Siphon Action; Large Pumping Plants; The Siphon Centrifugal Pump, 107.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, Idaho, Utah, Colorado, Oregon, Washington, New Mexico, 104-5.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 112.

#### Passing Events.

The thousands of visitors from the East and the interior who have enlivened San Francisco for the past two weeks have returned or are returning to their homes. The attractions of the State will keep many here, however, visiting points of interest, and doubtless some of those who came here will eventually settle in California.

Mining in Southern California seems to be in an advancing stage of progress. Some of the newer camps are doing very well, and the older ones are experiencing a revival of industry, leading to the reopening of old mines which are now worked at a profit.

The Legislature is still in session, but thus far has accomplished nothing toward the settlement of the irrigation question.

The report of the directors of the Mint for the calendar year 1885, just issued, shows that California still holds second place in the rank of bullion-producing States and Territories, being led only by Colorado.

Miners' associations are being formed in the interior of this State, though thus far no steps have been taken to carry out the suggestion of our correspondent, "The Old Man of the Mountains," to organize a State association.

THE *San Diegan* says: Prospectors to the number of 50 or 60 are in the vicinity of Campo, investigating the mining belt, and considerable excitement prevails over alleged discoveries of valuable mines.

#### Mining Profits.

In discussing the profits of the mining industry, fallacious arguments are often advanced, though the subject is comparatively simple. A profitless industry is one which pays nobody, or where the actual costs equal or exceed the actual returns. A mine which pays no dividends, but yields sufficient products to settle its accounts for wages and supplies, is not profitless. Agriculture in many regions does no more than support those engaged in it, yet no one would maintain for a moment that a county capable of supporting a given number of persons by farming, even though they were unable to accumulate a surplus, was not by so much richer than a country capable of affording a livelihood to no one.

The wages of miners are among the profits of the mining industry; so, too, is the surplus over actual cost of the industries which depend upon the mines for a market and that of the industries which depend upon the mines for supplies. The loss which would ensue if the mines were to be suddenly wiped out of existence is the exact measure of the profit which is now derived from them. In short, the entire profit of the precious-metal mining industry is the entire product in dollars, plus the increment (if any) of the value of mining property, plus the net profit of manufacturers of supplies used in the mines and of wares of the bullion produced; minus the net cost of supplies, including plant consumed in mining, and minus the shrinkage (if any) of the total value of mining property. The increment and decrement in the value of mining property (plant being counted under the head of supplies) can only be measured by the yield of the mines, which fluctuates greatly, but on the whole increases at an average rate of say two millions a year in this country. The gross expenditure for supplies other than plant is, say ten millions, of which, perhaps, 25 per cent may be counted as profit, and a similar sum probably represents the profits on the bullion in the manufacture of wares.

#### Foundry Notes.

The Fulton Iron Works have obtained the contract for building the machinery, etc., for the new ferryboat of the South Pacific Coast R. R. Co., to be used between this city and the narrow gauge pier on the Oakland side. The contract is quite a heavy one, of which we shall give further details shortly.

Work at the foundries in general continues rather dull, there being very few large jobs in the market. The labor difficulties have had some bad effects also, one of the large works having had to obtain their castings by rail from the East, it is reported.

The Council of Iron Trades and the Boiler-makers' Union have been considering the difficulties with the Union Iron Works at their meetings this week. At a meeting of the Representative Council of the Iron Trades on Wednesday a communication from the iron manufacturers, relating to the strike at the Union Iron Works was considered. A resolution was adopted stating that the council made the following proposition as a basis of settlement: Work is to be suspended for 48 hours to give the present workmen an opportunity to be admitted into the different iron unions. All those who are refused admittance are to have a hearing before a board of arbitration, whose decision is to be final. The arbitrators shall consist of two members of the council, two from the Employers' Association, and the fifth is to be selected by the other four. Should this plan be carried out the strike will be brought to an end. The council further agreed with a proposition from the Employers' Association that all further difficulties shall be submitted to arbitration.

JOHN FROST, who located the famous Oregon ledge in 1862, and has ever since been closely identified with that and the group of mines which were afterward merged in the Manhattan Company, died at Austin, Nev., this week. Mr. Frost has been kept steadily in the employ of the company as managing superintendent of all the surface works, hoisting and pumping machinery, etc. He was an excellent mechanic, and all the best mining machinery of the company has been constructed and erected under his supervision. In fact, he was next to the general superintendent in authority.

#### A New Mining School.

A new school, supported by the State of Michigan, is just being organized to furnish a thorough training in mining engineering, and will be opened on September 15th. The course of instruction will embrace geology, mineralogy, chemistry, mining and mining engineering, and such other branches as will enable students to obtain a full knowledge of the science, art and practice of mining and the application of machinery thereto.

Special advantages are offered by the situation at Houghton, in Houghton county, in the center of the "Lake" copper region, and within a short distance of Marquette, Menominee and Agogebic iron-mining districts. The surroundings present excellent opportunities for the study of actual mining operations conducted on a large scale, while the ground has become a classic one in the history of American geology. As provided by the statute organizing the school, tuition is free to students of Michigan. The regular course will occupy two years, with a post-graduate course leading to the degree of mining engineer after sufficient actual practice. Facilities for instruction, study and practice will be offered to advanced special students and those pursuing optional branches. For the present, however, the purpose is to confine the curriculum to mining engineering and metallurgy; and, further, to devote attention particularly to local interests, making specialties of iron, copper and salt—the three leading mineral products of Michigan—though not neglecting a study of the other important mineral substances, especially gold, silver, lead and coal, so that graduates leaving the State for other mining fields will be thoroughly equipped.

The general instructions will be by means of lectures, recitations upon the lectures, and textbooks, reading, laboratory and shop practice, field work in geology and surveying, inspection of mines and metallurgical works with actual practice. The course will contain geology, mineralogy, lithology, chemistry and assaying, mathematics, physics, mining metallurgy, surveying, drawing, and shop work. Under the head of mining it is proposed to teach the general systems followed in the different kinds of mining; the use of hand and machine tools; prospecting; development; hoisting, pumping and ventilating machinery; timbering; blasting; ore extraction; supplies; transportation, surface improvements; mine inspection; records, accounts and reports. Besides the technical points, mining will be considered as a business. The metallurgical course includes the questions of crushing and sizing, sorting, sampling, mechanical tests, ore dressing and concentration, roasting, amalgamation, leaching, smelting, fuels, fluxes, furnace products, refining, etc. The theory of the different processes, the construction and use of the various furnaces, machines and appliances, working tests and checks, and the proper selection of method according to the character of the ore, and the local and economic limitations, will be leading features. Experimental apparatus will be supplied by the State.

The principal of this new school is Albert Williams, Jr., formerly connected with the MINING AND SCIENTIFIC PRESS, and for some years past Chief of the Division of Mining Statistics and Technology, U. S. Geological Survey. Mr. Williams is a graduate of the Columbia School of Mines. During the preparation of the Census Reports he visited the mining districts of Montana, Idaho and Nevada, and spent a couple of years in the mining regions. Since then he has been engaged in preparing his annual report, entitled "Mineral Resources of the United States," which deals with all the mineral products of the country, except gold and silver. Mr. Williams has made not only a reputation for himself but for the department with which he was connected, by the thoroughness of his report. The work is the most practical of any issued by the Government, and has been of the greatest value to the mining community all over the United States. The scheme of the reports was laid out by him, and he had the task of putting into shape the material collected by his assistants. The Geological Survey loses a most valuable member of its corps by the resignation of Mr. Williams, and the State of Michigan gains an active and intelligent principal for its new mining school. Mr. Williams has already chosen J. D. Hoffman, formerly of this State, as one of his assistants,

and Dr. Packard as chemist, and the choice of the others is left also to him. He is now organizing the school, and his practical experience in the mining regions on this coast will be of great use in the matter, since he is familiar with all the requirements. We are pleased to see a Californian chosen for so responsible a position.

#### San Diego Mines.

About 1870 there was quite an excitement in San Diego county over the discovery of gold mines in Julian district, some distance back of the city of San Diego, on the mountains overlooking the desert. The writer was one of those who went to the camp at the time of its discovery. Several pretty good mines were found, notably the Owens, Stonewall, Helvetia, Golden Chariot. Another district called Banner was afterward discovered in San Felipe canyon, a few miles from Julian, where were discovered the Redman, Ready Relief and a number of other mines, several of which paid well on the surface, and then gave out, while others are still worked. The two districts are now one. The Chariot was at one time listed on the stock board. All the mines were worked for awhile, when many of them were abandoned or left idle; but not long since it was found they would pay under the better condition of affairs and better knowledge. From a state of partial abandonment the district has again become active, and many of the old mines are being reworked and paying very well. Some mines have been sold to Eastern capitalists, and St. Louis parties are now examining others. There are now seven or eight mills in the district, including that at the Stonewall, some eight miles from Julian. In the Owens a second ledge, at first unknown, was found at the depth of 300 feet; the two ledges formed one eight feet wide. The district is well wooded and watered, and the climate is good. The present condition of affairs is another illustration that we have not always been aware of the value of our gold-quartz industry. After lying idle for some years the mines are again worked, but more intelligently, and are found to pay well. In other parts of the State the same lesson is being learned.

#### Silver and Gold.

Silver has been declining steadily and rapidly for some time, and was as low as 90 cents per ounce last week, while the standard of pure silver is supposed to be \$1.29 per ounce. A slight improvement is now noticeable, however, and all the small lots of silver in this market were bought up this week by two of the banks at a higher price than was bid last week. This is an encouraging feature to silver miners. The low price of late has caused the shutting down of some low-grade ore mines on this coast, and more would have to follow the same course should the decline continue further. There is more confidence now that the metal will rise again, and that the lowest point has been reached.

The action of the Treasury Department in the matter of worn gold coins is creating considerable annoyance in this city. All coin showing signs of wear is now stamped "light" when received at the Treasury, and must be taken to the U. S. Mint and sold for old gold, at a loss from the real value of the coin. The consequence of this is that people are refusing to receive worn gold coins, and those who have them on hand will be losers. The matter has come up suddenly and entails an unfair loss on many. It would seem that when the Government issues the coin, which all the people handle until it becomes worn, the Government should redeem it for its full value, letting whatever loss there is fall on the whole country rather than the individual who happens to possess it at the time an order is made to declare it "light."

THE pulverizing room of the California Powder Works, near Santa Cruz, was burned on Monday. The processes of powder manufacture are conducted in detached buildings, and the fire was confined to the building in which it originated. The machinery destroyed was very valuable and the loss will reach several thousand dollars. The company have a duplicate mill of the same character, consequently the works will not be compelled to stop.

## Drift Mining of California.

[By RUSSELL L. DUNN, M. E., of Auburn, Placer Co.]

Out of the peculiar conditions of situation of the auriferous gravels of California has been developed the method of mining generally termed "drift mining." Owing probably to its exclusive localization in California, and its comparatively slow development as one of the leading branches of the gold-mining industry of the State, is due the absence of much definite published information concerning the practical details of its operation. Also has it been to a less extent than any other branch of mining the subject of study and scientific investigation by trained mining engineers. In this article I have taken the experience of the practical working of many of the old and successfully operated mines, and from it have made such general deductions as will be of assistance in the exploration and development of new claims.

The drift-mining districts of California comprise practically the entire areas in the State containing the unworked out gold placers, and are part of the western slope of the Sierras included within the counties from Mariposa on the south, Shasta and Siskiyou on the north. It is in Nevada, Placer and Sierra counties that the most extensive areas of mining ground are found, and also the at present most important mines being worked. Plumas, Butte, El Dorado, Amador, Calaveras and Tuolumne counties have also considerable areas of mining ground and important mines.

The geological character of this entire district is uniform throughout its entire extent. The main axis of the Sierras, and including the western slope to a distance from 10 to 30 miles from the summit, is granite. From the western edge of the granite, and overlying it from thence and extending to and disappearing under the alluvial plains of the valley, is an immense body of metamorphic stratified rocks. Of these, slate forms by far the larger part, limestone being the next most important. In a large area of Western Placer, Nevada and El Dorado counties, granite appears at the surface and is the country rock. The general topography of the country must have been rough, but hilly rather than mountainous. The river depressions do not seem to have been deep precipitous gorges and canyons, as at present, but apparently the streams run in beds very near the general level of the country. These ancient rivers were, judging from the disconnected fragments of their channels that have been explored in mining, comparatively short streams, but in some instances of great width and carrying large bodies of water.

In some localities two distinct sets of ancient river channels have been found, one cutting across the other, and so differing in every essential characteristic that they were undoubtedly formed during widely separated periods of time. All of these old stream channels necessarily became more or less filled with the detritus of their erosion. In some the debris consists almost exclusively of quartz, boulders, gravel, and sand; others, again, are marked by almost an entire absence of quartz, its place being taken by granite, slate, and lava, gravels, sands and clays. In nearly all of these gravel-filled channels was gold, gathered from the eroded auriferous quartz veins and seams. This, briefly stated, was the physical condition of this country during the Pliocene period and until a great lava flow swept over the surface and covered it from one or two hundred to as many thousand feet deep. This lava flow followed and became, of course, deepest in the channel depressions, but was still deep enough to cover nearly all the elevations as well. It closed the period of the old physical conditions and topography of the country and was the commencement from which this present topography dates. The present streams, principal among which, as draining the largest and most important part of the mining area, are the Feather, Yuba, and American, with their respective forks and branches, have gradually eroded tremendous canyons, in which they run one, two, and even three thousand feet below the summits of their precipitous sides. Their general course, more particularly in the region of the lava-covered old river channels, is, if anything, more westerly than the latter, though this is by no means invariable, the direct reverse of this being true in some localities and in others the courses being parallel. The erosion cut away first the lava,

then the gravel drift in the buried channels, and finally far into the hard slates. The gold eroded out of the old channels, and some from the direct erosion of quartz veins, enriched the ravines, river beds and bars, making the rich placers from which immense sums were taken during the early years of the California gold mining. These were long since practically exhausted and abandoned, and the source of the placer gold at present being taken out and still valuable for the mining of future years, it is to be found in the fragments of the old river channels and drift left by the erosion of the present rivers lava-buried in the high divides or mountain spurs between the extremes. These divides are from a few hundred yards to several miles in width, comparatively level, except for a light upward grade toward the main mountain axis. The small tributaries of the rivers run on these divides in shallow depressions on easy grades until they reach the precipitous canyon

became too large to admit of economical handling. Accordingly, to afford natural drainage, and also to secure easier carriage for the gravel from the mine to the surface, where it was washed, tunnels were run in the bedrock on a light-ascending grade, and at such depths as it was supposed would leave it lower than the lowest point it was designed to work. From this time drift mining became recognized as a distinct branch of placer mining.

The annexed diagram is intended to represent, typically, a portion of one of the lava-capped divides containing an old river channel, as illustrating the methods of prospecting and mining. The large cut shows contour lines of surface. The shaded ground represents contours of bedrock, or country rock. The unshaded ground is lava. The vertical distance between contour planes is 50 feet; scale, 800 feet to an inch. The smaller cut shows profile line of cross section. The shaded ground is bedrock;

LAVA COVERED "OLD CHANNELS," SHOWING CONTOUR LINES OF SURFACE.

PROFILE LINE OF CROSS SECTION.

sides down which they plunge in cascades and waterfalls.

The genesis and history of the deep placers, as they are sometimes termed, have been given in this article at considerable length, as in them are much general data that can be practically applied in mining them. The original discovery of the deep placers of the ancient river system occurred in the working of the ravines and gulches by the early miners.

They kept prospecting and working up higher on the mountain-sides in search of the source of gold, and finally reached points beyond which it was impossible to find any traces of it on the surface. At these points they found auriferous gravel going into the mountain, and by means of short tunnels run following the pay on the surface of the bedrock, they mined it. It was, however, soon discovered that in going into the mountain, the bedrock, instead of keeping on an ascending grade, pitched away from the face of the mountain on a descending grade inward, and, as a consequence, the influx of water into the working, having no natural drainage, soon

unshaded, lava; A, B, beds of old river channels; M, N, tunnels; X, Y, shafts; vertical scale, 800 feet to an inch.

Surface indications of the presence of an old channel are not always to be found. In case the channel runs directly or diagonally through the divide or mountain spur, at the points of ingress and egress, gravel rich in gold is often found in large quantities, and this, with other indications in connection with it, is considered conclusive evidence as to the locus of the channel. More often, however, as in the case with the two channels indicated in the diagram, they run with the divide, and with entrances so far removed from the ground under examination that they cannot be identified as connected with it, and would be useless if they could, in which instances there is absolutely no direct evidence of the existence of a channel, and it for the time being must be regarded as suppositious or reasonable from analogy. Often these latter-described channels are located so close to the front of the mountain that the ravines and gulches, while not cutting through

them, have crowded so close as to remove some of the gravel and present the indications of a channel entrance. Some of the richest drift mines of the State have been located by tracing up these "break-outs," as they are termed.

If the surface on one of these divides be examined carefully and surveyed and platted, showing the true contours and line of junction of the bedrock and lava (or, as it is locally called, cement), it will, in its general features, resemble the annexed diagram. It will be observed that the surface line of junction of the two formations does not align with contour lines on the surface, but shows considerable variation in relative altitude at different points, and it is this fact that makes it possible to approximate to the varying locus of the hidden channel, other conditions dependent on ascertainable data being favorable. The high bedrock lying between the channel and the face of the hill on both sides is commonly referred to as being the "rims" or "rim-rock" of the channel. Two channels on the same divide, which are of frequent occurrence, each having only the outer rim visible at the surface, complicate considerably the solution of the problem referred to previously, and the approximate determination of the locus of the buried channel by engineering methods alone, and will often render it impossible.

Considering the case delineated by the diagram, suppose a number of cross-sections be made in lines parallel to the line marked "line of cross-section," at supposed right angles to the line of the channel sought for, and at, say, 250 feet apart. In each of these that would cross the upper portion of the diagram, where in each of the channels both rims come to the surface, there would be given the horizontal distance between the point of intersection of the rims with the surface and their difference of level. With two more conditions given, the slope of the rims forward, and the width of the channels, its location in that particular section line could be exactly determined. As to the mean slope angle of the rims, it must be so taken for trial that on applying it in calculation it will locate the channel depression symmetrically between the rims. It is a matter of judgment of the engineer with reference to the ground that is being examined, and it is advisable to try maximum and minimum limits. The probable width of the channel can only be guessed to its most probable figure. A knowledge of the known channels of the locality is the safest guide. The highest maximum of mean slope should not exceed 30°, and for width of channel not over 500 feet. Now, with the data already discussed, the horizontal distance from the surface point of the upper rim to the approximate center of the channel will be equal to one-half the distance from the first-named point to the point in its plane at which the mean slope line passing through the lower rim surface point would strike, the slope angle being the same for both rims, and the difference of level between the plane of the upper rim point and the depression of the channel equal to the half distance referred to above into the tangent of the slope angle, diminished by one-half the assumed width of the channel into the tangent of the slope angle. The graphical method is best suited for obtaining these quantities, no great degree of accuracy being required. The same rules being applied to the other cross-sections, a series of line and grade points will have been obtained, and by comparison an average can be obtained which will check out unconformable extremes, and will also determine points where only one rim is available, as is the case illustrated on the diagram. Having platted the presumed course and grade of the channel on the topographical map, the engineer can readily determine the points from which the channel can be prospected most thoroughly and economically, and, if found to contain enough gold to pay for opening and working, the best available point for that purpose, making use of the additional and exact data acquired in the prospecting.

It will at first consideration seem that, using such inconstant factors and unknown variables as can only be had under the circumstances, it would be impossible to place any reliance on the results so obtained. Such, however, is not found to be the case in practice. The limits for error are usually easily determined, and it is very rarely that an extreme case similar to the hypothetical one considered in this article will occur. More or less underground work can be

Gwynne connected its pumps by means of a tube and globe valve with the condenser of the steam engine; the engine is first started in order to create a vacuum in the condenser, and as soon as this is effected the globe valve is opened, when the water rises in the suction pipe. As soon as the water fills the revolving runner, the labor of the engine is greatly increased, and would cause it to stop if the engineer did not prevent this by opening the steam valve."

(It may be stated as a matter of curiosity that the latest catalogues of that firm carefully avoid mentioning the neat little way by which it primes its pumps, avoiding suction and discharge valves; can it be that Mr. Huet has been telling tales out of school? If so, we have reason to be very grateful to him.)

"No difficulty whatever is now experienced in priming the centrifugal pump; they are now universally placed at a considerable height above the level of the inside water, and the main objection against their use in draining low lands has thus been overcome. It might occur, however, that the water had to be raised higher than was required, as has been the case in the drainage of the Lutke sea. This difficulty, however, is overcome by bending the discharge pipe downward to a point below low water, giving it the shape of a siphon; hence the name siphon-centrifugal.

"The most important change, however, in the centrifugal pump during the last years is without doubt the direct connection of the shaft of the engine with that of the pump, making both one shaft; in this manner the transmission of power by belts, which requires much room, is avoided, and also that by gearing, in the use of which shocks and breakage are likely to occur.

"By this new arrangement room is also saved for still another reason, to wit: Inasmuch as a steam engine acting directly on a pump must be constructed to make a great number of revolutions per minute, one of quite limited dimensions will give the power required. The suction pipe is usually made as short as possible; the most usual arrangement is that adopted in the construction of the pumps constructed in 1875 and 1881 respectively by J. A. Van der Kloes, C. E., at present professor at the Polytechnical University, the one at de Myl at Dordrecht, the other at Delft." (The Pearson district pump follows closely the drawings of these pumping stations. They are contained in the collection of maps above referred to.)

"Barring some small, unimportant modifications due to local conditions, the arrangement of siphon-centrifugal steam pumps is in all essential points always that referred to."

(Prof. Huet wrote his book in 1885.)

"The entire arrangement of the direct acting siphon-centrifugal is a *chef-d'œuvre* in mechanical engineering, which deserves, in many respects, our highest praise; for, by reason of the great piston speed obtained the fast-moving and revolving weights co-operate with the runner filled with water to regularly produce great smoothness of action, all of which is obtained by an arrangement by which advantage can be taken of great steam expansion."

Considering the fact that English, German, French and Italian engineers all seem to agree on one point, to wit: that whenever they have to do anything with water, raising it, fighting it, draining it, or doing anything else with it, they either go to Holland and see how it is done there, or send for a Dutch engineer to do it for them, I think the statements made by Mr. Huet authorized me to write: "That the siphon-centrifugal is now adopted in all large reclamation works in Europe, to the almost entire exclusion of the system formerly applied." It is difficult to take up a Dutch newspaper now which does not state in some way or another that such and such polder is about to construct a siphon-centrifugal instead of its old-fashioned plant. As Mr. Richards wants cases cited, a few are given below; their number can be enlarged at pleasure.

The pumping plant erected at the Stadil fjord; the pumping plant erected at the Stadtpolder, near Dordrecht, in 1881, and that *aan de Myl*, by Dordrecht, in 1875; in addition to the above it may be added that Mr. Huet gives a plan for a direct double-acting, siphon-plunger pump, which he believes could be made to give a higher duty than is yet attained by any siphon centrifugal; the engine and pump are placed above the level of outside water, and the discharge-pipe is projected to gradually widen and to siphon the water to a point below low water; plans and specifications of all of which are at Mr. Richards' disposal. Also, the largest pumping plant in the world, that erected in 1874 by John and Henry Gwynne for the drainage of the Ferrara marshes, discharging 456,000

gallons per minute (see plans in illustrated catalogue of that firm); the 36 siphon-centrifugal, erected by the last-named firm in 1879 for the Sijfoji Inland Water Regulation Company, Hungary (see page 39, catalogue.) I think it will now be in order for that gentleman to come forward and cite us his cases supporting his statement: "that the practice (the siphon action of discharge-pipes) has fallen into 'desuetude' from the face of experience."

III. I confess my ignorance as to the antiquity of "iron pipe," but granting that the idea is as old as say "marriage," that would in itself not prove anything against it; the latter institution is a far from recent innovation and, in most cases at least, it is found to work quite pleasantly; but here again my information does not agree with that of my learned friend, and he will confer a great favor by citing the authority on which the statement, "the idea (of siphon action in discharge-pipes) is as old as iron pipe," is made.

Yours sincerely,  
P. J. VAN LOBEN SELS.

San Francisco, Aug. 6, 1886.

[FROM MINING AND SCIENTIFIC PRESS, JULY 10, 1886.]

### Siphon Action.

EDITORS PRESS:—In your issue of June 5th there is a description of a draining pump made by the San Francisco Tool Co. and some statements respecting such pumps which many of your readers will construe as coming from myself, because of my connection with that company.

This I wish to correct and to add that I am wholly opposed to siphon action in the discharge pipes of any pump unless unavoidable,

ards' letter are reprinted in this number of the Press, and also the reply from Mr. Van Loben Sels. We trust other engineers will come forward and express their opinions on a subject which just now seems to become of paramount interest to the welfare of this State.

[FROM MINING AND SCIENTIFIC PRESS, JUNE 5, 1886.]

### The Siphon Centrifugal Pump.

#### Machinery for Draining Large Tracts.

The San Francisco Tool Company, which has been for some time making a specialty of irrigation and drainage machinery, is now manufacturing a siphon centrifugal pump, combining many advantages over others yet devised for the drainage of large tracts of land. The siphon centrifugal is now adopted in all large reclamation works in Europe, to the almost entire exclusion of the system formerly applied.

Its main features are the connecting of the runner of the pump in a direct manner to the main shaft of the engine, on a level above any possible flood-water; the discharge pipe is conducted over the levee down to a point below the lowest possible low-water mark of the outside stream. No foot or discharge valves of any kind are used, avoiding all friction otherwise inevitably caused by valves. The pump is charged by means of the vacuum created by the condenser. When the pump is stopped, a water-gate, placed at the discharge of the pump, prevents the outside water from siphoning over the levee into the district; the pump, in the meanwhile, remains charged or primed. For the sake of economy of coal, the use of a

given circumstances, which can be increased from a minimum of say 10,000 gallons per minute to a maximum of 60,000 gallons per minute. In practice, of course, actual experience will show which rate of speed will, at a given height, give the most economical results in the consumption of fuel.

This engine has, like all other engines made by this company, received the greatest possible care in its design and workmanship. The working parts are reduced to the fewest number possible without sacrificing its efficiency, and are thoroughly balanced, enabling the makers to guarantee their engines to run at a very high speed. The bearing surfaces are of exceptionally large area, and the lubricating arrangements most perfect. The most of the forged parts are of the best hammered steel, and all the materials used in their construction, as well as the workmanship, are of the best description.

The average of several tests made May 24th and 25th, conducted personally by the agent of the reclamation company, showed its capacity to be 37,907 gallons per minute, at a lift of 11 feet 7 inches, the engine indicating 156-horse power, with a consumption of 4.4 pounds average Sydney coal per actual horse-power of water raised per hour—the most satisfactory and economical showing so far made by any pumping plant.

This plant was constructed for the drainage of the Pearson Reclamation district, in Sacramento county. The order was received on the third day of February, when all plans, patterns, etc., had yet to be made. The entire plant was in running order on the tenth day of April following. The foundation consists of 50 piles, 40 feet long, driven to the hardpan. We are informed that the entire cost of the plant,

including engine-house, two boilers, 16 feet by 90 inches diameter, and foundation, does not exceed \$20,000, for which sum the Tool Co. thinks it can be duplicated. When such a degree of perfection and such results are now attained by a home company which guarantees all its engines, pumps or tools, and their satisfactory condition, it seems foolish to order from the East from people who are not familiar with local conditions, and whose interest ceases on the delivery of the shipping receipt.

The Pearson Reclamation district is one of the largest and most successful reclamations on this coast. It consists of 8800 acres of very fertile land surrounded by a superb levee of an average height of 18 feet, 15 miles long. During the extraordinary freshets and floods of last winter, the pumping plant, formerly constructed by the San Francisco Tool Company, and consisting of two 15-in. pumps,

constructed for its drainage, proved entirely insufficient to cope with the large body of rain and seepage water. On the 20th of April about 2000 acres were covered with water from 6 to 12 inches deep and 350 acres thereof forming the bed of a lake 5 feet 8 inches deep. Notwithstanding the heavy rains in the latter part of April, and the formidable amount of seepage finding its way through the solid earthen embankments, the 30-inch siphon centrifugal has now drained the entire district, all those lands being now covered with growing crops, even the lake bed being cultivated at the time of this writing.

The pump here illustrated and described is at present pumping the water 14 feet (the difference between the inside and outside water levels), while the inside water is 24 feet lower than the top of the pump. No difficulty whatever is experienced in holding the pump full of water by means of the vacuum, at either a high or low speed of the engine.

Although the San Francisco Tool Company is prepared to construct pumps of every description, and to fill any order which may be given it, we are informed by the company that it believes the siphon centrifugal to combine the greatest advantages, and therefore recommends it to their patrons, by reason of the high duty it insures, the permanency of its construction, the economy of first cost of construction and great saving of running expenses and delays effected. Among the notable advantages insured by this system are the following: 1st. The engine and the pump are above the level of flood-water, avoiding the danger of the inside water, in case of a break in the levee or excessive rain-water ruining the plant or preventing the running of the pump. 2d. The pump being connected directly to the engine, avoids the use of all gearing and belts, at best a nuisance, and the weakest and most expensive part of any plant, causing constant stops, breakage and expense. 3d. The siphon prevents the pump from at any time raising the water higher than the exact difference between the two water levels, even enabling one to take advantage of

THE SAN FRANCISCO TOOL COMPANY'S SIPHON-CENTRIFUGAL PUMP.

as it may have been in the case alluded to.

The statement respecting the arrangement of pumping on this method in Europe "to the exclusion of other methods formerly applied" will be news to those there who erect such machinery. The idea is as old as iron pipes, and the practice has fallen into "desuetude" from the face of experience. No cases being given, I am at a loss to know where the plan has been revived.

The agitation of water in passing through a pump of any kind releases air which lodges in the discharge pipes, and unless continually drawn off by some negative pressure, equal to the difference in the water levels, the siphon action soon ceases.

The employment of a condenser or steam ejector to remove this air takes draining apparatus from the field of simple mechanism so desirable in such cases, and offsets the counterbalancing of advantages.

Instead of such a method coming into use in the Old World, I think no maker of such machinery will, when avoidable, raise water above a discharge level. As before said, I am not aware of the authority on which the statement is made, but must recommend it be taken *cum grano salis*, at least I want no part in its paternity.

J. RICHARDS.  
Pittsburg, Pa., June 25, 1886.

### Large Pumping Plants.

On June 5th we published a description of a large pumping plant lately erected in this State. Its construction deviated widely from the manner heretofore adopted; it called forth some criticisms from a well-known engineer, and our present issue contains a reply from the author of the first article.

In view of the fact of the great importance of the subject, and believing our readers will be pleased to find the various arguments in one issue, both the original article and Mr. Rich-

compound-condensing engine is recommended. Large hand-plates in the sides of the pump facilitate the examination and cleaning of the runner.

The accompanying engraving represents a 30-inch siphon centrifugal pump, connected directly to a compound-condensing engine with variable expansion gear, the latter enabling the engineer, without a moment's loss of time, to change the point in the stroke at which the steam is cut off, and to modify the speed and power of the engine as the change of lift or quantity of water desired to be discharged requires.

This engraving was copied from a photograph taken at the moment the engine was ready to leave the works of the Tool Company for shipment. The gate at the discharge, the suction and discharge pipes, are not shown. The relative positions of the two steam cylinders, the fly-wheel, heater and jet-condenser, clearly appear; also the connection on the top of the pump with the condenser for the purpose of priming the pump and removing any air which might gather there, by reason of possible leaks or from the air always contained in water. The pipe also furnishes the water for the jet condenser, which is supplied to it from a point sufficiently high to relieve the condenser pumps of all work of raising it.

The diameter of the fly-wheel is 58 inches; that of the low and high pressure cylinders 14-inch and 26-inch respectively. In this instance the diameter of the discharge pipe was increased from 30 inches to 40 inches, immediately after leaving the pump, and that of the suction pipes from 23 inches to 28 inches, insuring a small amount of friction (the water running through the pipes at a velocity of 93 feet per second when discharging 38,000 gallons per minute), which arrangement will speedily save in running expenses the slight excess of first cost incurred. The stroke is 18 inches. The number of revolutions is from 130 to 210 per minute, according to the height the water is to be raised or the quantity desired to be discharged under any

the daily changes of the tide-water. 4th. All the working parts of the engine and of the pump are inside the engine-house and above its floor, and within easy reach of the engineer, who can, without disturbing any other part, adjust any part of the engine and remove either manhole plate or side-plate of the pump within two or three minutes. The great delays and expense experienced in cleaning, examining or repairing submerged pumps are thus avoided. 5th. It obviates all earthwork or interference with the levee (always dangerous), and all masonry or bulkheads. 6th. By opening the gate a means for irrigation during the summer months is furnished, as the outside water will at once be siphoned over the levee into the district, a most important feature for reclamations in California.

Mr. P. J. Van Loben Sels, the agent of the reclamation district, is highly pleased with the operation of the pump, and testifies to its efficiency and the results referred to above.

### Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

**WHIFFLETREE HOOK.**—Geo. C. Johnson, Fort Bragg, Mendocino Co. No. 346,590. Dated Aug. 3, 1886. This invention relates to a new and useful clip-hook of that class in which a swinging hook overlaps and finds a seat upon a fixed hook, the two forming a ring or link in which the connecting hook, ring or link is confined; and the invention consists in the novel joints formed between the two hooks when engaged and in the peculiar bearing or support for the pivoted end of the swinging hook, together with the general arrangement of parts. The object is to provide a readily-applied connection between a single-tree and the trace, or between a double and single-tree.

**ADJUSTABLE CONNECTION FOR BRAKE-BEAMS.** J. M. Walsh and C. G. Smith, Taylorsville, Plumas Co. No. 346,333. Dated July 27, 1886. In this improvement on wagon-brakes, a connection is made by which the brake-beam may be readily adjusted in order to bring its shoes into proper relation with the wheels. It consists in the adjustable toothed or rack-bar forming one of the system of brake-operating levers and rods, and the pivoted pawl-lever engaging and fixing the adjustment of the rack-bar. Usually the operation of adjusting the brake-beam is long and difficult. The operator has to get under the wagon and with a wrench adjust or relieve the various nuts and bolts in order to change the position of the beam. This difficulty is obviated by this invention, as the work can be easily reached and quickly accomplished.

**WATER FILTER.**—Anthony McLean and Findlay Cumming, S. F. No. 346,304. Dated July 27, 1886. This filter is to be attached to ordinary pipes or faucets for the purpose of cleansing water to be used for household purposes. It consists of an exterior transparent casing and an interior cylindrical column, the sides of which are formed of filtering material, and having a central discharge opening in the bottom. The upper end is screw threaded, and in combination with this is a shank extending upwardly so as to enter the mouth of the faucet, and having connected with it an eccentric, corrugated or other suitable locking device, by which it is held to the faucet, while it is screwed in place, a joint being made by a suitable elastic packing at the top of the outer casing.

**WHIFFLETREE CLIP.**—Geo. C. Johnson, Fort Bragg, Mendocino Co. No. 346,589. Dated August 3, 1886. This clip and swiveled-hook connection consists in a curved clamp or clip for embracing a whiffletree, and having parallel separated jaws; a hollow or tubular bolt passing through the upper jaw and screwed into the lower jaw; a nut seated on top of the bolt, whereby it may be made to tighten up the clamp upon the whiffletree; a block or piece pivoted loosely on the bolt between the jaws; an eye-bolt swiveled in the block or piece, and a hook connected with the eye-bolt. The object of the invention is to provide a simple and effective means for readily attaching and detaching a double-tree to and from any implement without the use of a clevis, and for attaching it to the pole of a vehicle, or for attaching a single-tree to a double-tree.

### Orchards and Vineyards on Debris.

**EDITORS PRESS:**—Having just returned from Amador county, I have to communicate a few facts touching the debris question. I found some of the most flourishing orchards and vineyards on made ground collected by the hard-working Italians from impounded slickens. Such prodigious luxuriance of fruit and foliage, it has seldom been my good fortune to inspect. One and all whom I questioned stated that they did not want hydraulic mining stopped. This is an aspect of the question as agreeable as unexpected.

W. S. KEYES, M. E.  
Member Board of Trustees, S. M. B.

The amount of bullion that comes in from White Pine and Lincoln counties is largely increasing.

### COST OF REFINING 89,394 LBS. RETORTED BULLION.

(See Article on Page 97.)

			Per Cent.	Per pound bullion.	Per pound bluesome.
			Cents.	Cents.	Cents.
Roasting, crushing and sulphurizing.....	(Wages, 575 shifts @ \$3.10..... \$1,629.06 Fuel, 86 cords @ \$7.85..... 676.14 Sulphur..... 60.94)	\$2,365.14	15.1	2.65	0.79
Dissolving.....	(Wages, 586 shifts @ \$3.70..... \$2,166.50 Fuel, 240 cords @ \$7.85..... 1,883.63 Acid, 3,023.65 lbs. @ 1.33 cents..... 4,031.15)	8,083.28	51.7	9.05	2.68
Concentrating.....	(Wages, 27½ shifts @ \$3.50..... \$96.25 Fuel, 77 cords @ \$7.85..... 604.62)	700.87	4.5	0.78	0.23
Crystallizing and packing.....	Wages, 160 shifts @ \$3.58.....	572.09	3.7	0.64	0.20

Total manufacturing cost.....		\$15,632.57	100.0	17.48	5.27
Copper, 48,039 lbs., paid for @ 15 cents.....		7,205.85		8.06	2.38
Total amounts charged.....		\$22,838.42		25.54	7.65
Wages, 1451 shifts @ \$3.49.....		\$5,059.48	32.4	5.66	1.70
Material.....		7,621.90	48.7	8.52	2.54
General.....		2,961.19	18.9	3.30	1.03
		\$15,632.57	100.0	17.48	5.27

Of the total cost, including copper (\$22,838.42), wages constituted 22 per cent; material, 65 per cent; general, 13 per cent.

### Book Notices.

**RAILWAY OFFICIALS AND DIRECTORS.**—We have received through A. L. Bancroft & Co. "Poor's Directory of Railway Officials and Railway Directors." It is a new work by the publishers of "Poor's Manual of Railroads." A brief summary of its contents will show its value to the industrial interests of the country: 1. A list of the officials of every railroad in the United States, Canada, Mexico, Central America, South America, West Indies, Great Britain and Ireland. 2. A list of the officials of street railroads in the same countries. 3. A list of the directors of all railroad companies in North America, alphabetically arranged, with their addresses. 4. A list of the officials of organizations auxiliary to the railway system, such as fast freight lines and transportation companies, bridge and union depot companies, packet, steamboat and steamship companies, parlor, sleeping-car, equipment, express, and telegraph companies, etc. 5. A list of the officials of industrial establishments dependent on the railway system, such as locomotive, car and bridge works, rail mills, etc. 6. A list of the officials of the leading exchanges and commercial associations throughout the country. 7. A list of the leading contractors throughout the country whose specialty is the construction of railroads and works connected therewith. 8. A list of the officials of new railways now in progress in the country. 9. An alphabetical list of the officials of all the American railways, with a convenient system of reference showing the lines with which they are connected.

This work contains the names of 30,000 persons occupying important official positions, and gives addresses of those permanently associated with the railway interests of the country. The work is neatly printed and bound and is a very useful one for many persons.

**THE TECHNO-CHEMICAL RECIPT BOOK.**—Henry Carey Baird & Co., of Philadelphia, have just issued a very useful hand-book, with the above title, containing several thousand receipts, covering the latest, most important and most useful discoveries in chemical technology, and their practical application in the arts and the industries, edited chiefly from the German of Drs. Winckler, Elsner, Heintze, Mierzinski, Jacobsen, Koller and Heinzerling, with additions by William T. Brannt, graduate of the Royal Agricultural College of Eldena, Prussia, and William H. Wahl, Ph.D. (Heid.), secretary of the Franklin Institute, Philadelphia; author of "Galvanoplastic Manipulations." The work is in one volume of 495 pages 12mo, and is illustrated. The principal aim in preparing "The Techno-chemical Receipt-book" has been to give an accurate and compendious collection of approved receipts and processes of practical application in the industries, and for general purposes. The work is essentially what it claims to be—a receipt book—and all theoretical reasoning and historical detail have been omitted. Popular and simple descriptions have, wherever possible, been preferred to technical and scientific language. The materials have been principally derived from German technical literature, which is especially rich in receipts and processes which are to be relied on, most of them having been practically tested by competent men before being given to the public. In the laborious task of translation and compilation, only the best and latest authorities have been resorted to, and innumerable volumes and journals consulted, and wherever different processes of apparently equal value for attaining the same end have been found, more than one has been introduced. This little work is one

which will be found handy for reference to almost every one, no matter what business or trade they may be engaged in. It is very completely indexed, and covers more branches than we have space to enumerate.

**MODERN STEAM ENGINES.**—Joshua Rose, the well-known writer, has produced a new book which will be much sought for. It is published by Henry Carey Baird & Co., of Philadelphia, and is a treatise on the steam engine, written in plain language, for use in the workshop as well as in the drawing office. It gives full explanations of the construction of modern steam engines, including diagrams showing their actual operation, together with complete and simple explanations of the operations of various kinds of valves, valve motions, and link motions, etc., thereby enabling the ordinary engineer to clearly understand the principles involved in their construction and use, and to plot out their movements on the drawing-board. The work is illustrated by 422 engravings and is sold for \$6. The diagrams explaining the action of each valve motion have been obtained by moving the engine throughout a revolution, and measuring the port openings both for admission and exhaust, at each inch of piston motion. These diagrams, therefore, represent the actual workings of the valves. Where a certain mechanism is to be considered, the engravings first show it as a whole and explain its general action. It is then treated in detail and moved through its various positions, a separate engraving showing each new condition, and a diagram showing the action under each condition. The engravings have been made large, and, in many cases, repeated, so as to render them easy to follow and avoid turning to back pages. The author has endeavored to omit nothing that is essential to those who may begin their studies of the steam engine from the pages of this book. All classes of engines are treated, including portable, marine, fire, pumping, compound, etc. Each subject is complete in itself. The work is full and clear in its treatment and easy to follow. The engravings are of good size, and the typographical appearance of the book excellent. No more complete elementary work of the kind has previously been published, and any one interested in steam engines will find its pages full of valuable material.

### March into Line.

**EDITORS PRESS:**—That the miners of this State should organize is a foregone conclusion, now since the water question has come to the front. The press of the State all talk water for irrigation; the miner and his rights has no consideration, no matter how much money he has expended in ditches or on his mining properties. Since my call for organization I see Plumas county has organized, as is shown in the following item:

The Plumas county miners have formed an association known as the "Feather River Miners' Association." N. Cadwalader is president and treasurer, H. M. Barstow secretary, and Hon. J. D. Goodwin, N. Cadwalader and A. Hall constitute the Finance and Executive Committee. This association has issued a circular to interested parties in Plumas.

If every county of this State has its local organization they will find great good come from it in more ways than one; so organize. There is a coming contest on this water question which is life or death financially to many a miner.

THE OLD MAN OF THE MOUNTAINS.  
Murphys, Calaveras Co., Cal., August, 1886.

### About Obtaining Patents.

#### Patents are Virtually Contracts.

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence, it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, in order that it may afford him complete protection for his invention during the life of his patent.

#### Secure a Good Patent.

An inventor should first ascertain whether or not his improvement has been patented to another. This requires an exhaustive search among all the patents in the class to which the invention relates. If, by this "preliminary examination," the improvement is found to have been previously invented, our client will receive, for the small sum of \$5 for the examination, a verbal or written report showing definitely wherein his invention has been anticipated, thereby saving him further expense and perhaps much time, anxiety, etc.

To avoid all needless delay, however, and secure patents at the earliest moment practicable, inventors will do well to forward a model, drawing or sketch, with a plain, full and comprehensive description of their invention (stating distinctly what the particular points of improvement are), with \$15 as a first installment of fees. If the improvement appears to us to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately and forwarded to the inventor for his signature. When he receives the application and finds it duly prepared, he will carefully sign and return the same plainly addressed to us, with postal money order or express receipt for our own fee. The case will then be promptly filed by us in the Patent Office, and vigorously prosecuted to secure the best patent possible. [This course is the most expeditious and satisfactory, as no time is lost in transmitting correspondence relative to the preliminary steps.] When the patent is allowed the inventor will be duly notified, and on sending the final Government fee of \$20 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

The payments are thus divided and made easy. We make no pretense of doing cheap work, in order to entice custom, nor do we afterward make additional charges to bring the bill up to a fair compensation. We do our work honestly and thoroughly, and we never give up a case so long as there is a chance of obtaining a patent. The Agency charge, including drawings, rarely exceeds \$40, and for this we do all we can without appealing the case.

#### Models and Drawings.

Models are now seldom required by the Commissioner of Patents, and generally only in intricate cases. Perfect drawings of practical working machines are more satisfactory to the Patent Office than the old cumbersome system of storing up an immense bulk of countless models.

Drawings or sketches, sufficient to illustrate the invention clearly, with a description that will enable us to make a full set of perfect drawings for the Patent Office, is all that we require. A model will answer our purpose as well, however, in cases where the inventor can more easily furnish it.

The value and even the validity of a patent often depends on the character, clearness and sufficiency of its drawings. There are thousands of existing patents in which the improvements are but partially or poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the vagueness and defects of the drawings often prejudice capitalists and manufacturers against the invention, while in reality it may be of great value, and would meet with ready sale had it been skillfully, completely and artistically portrayed. In all cases prepared by us, the drawings are made under our personal supervision, by skilled draftsmen in our constant employ, and every precaution is taken to have the invention fully and clearly shown by different views, so that the improvement will be readily understood by the Examiners in the Patent Office, and comprehended by the public when the patent is granted.

#### Advantages to Inventors on the Pacific Coast.

The firm of DEWEY & Co. has edited and published the MINING AND SCIENTIFIC PRESS continuously since 1860, a period of 26 years. Few agents, who are still engaged in the business, have had so long-extended practice in patent soliciting. The members of the firm give personal attention to the applications entrusted to their care; and their familiarity with inventions and with local affairs in the Pacific States and Territories, enables them to understand the wants of inventors on this coast more readily and thoroughly, as we believe, than any other agents in America. Thus there is saved a great deal of the time which ordinarily—when distant agents are employed—is wasted in preliminary writing back and forth.

This happy combination of long business experience together, and wide connections, has placed our firm in a position unquestionably most fortunate for affording inventors prompt and reliable advice, and the best facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly-stated and correct description of his invention, in one or more of our influential and reliable newspapers, affording just the circulation best calculated to widely inform the class of readers especially interested in the subject of his invention.

#### Caveats.

A Caveat is a confidential communication made to the Patent Office, and is therefore filed within its secret archives. The privilege secured under a caveat is, that it entitles the caveator to receive notice, for a period of one year, of any application for a patent subsequently filed, which is adjudged to be novel and is likely to interfere with the invention described in the caveat, and the caveator is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from \$10 to \$20. The Government fee is \$10 additional.

To enable us to prepare caveat papers, we require only a sketch and description of the invention.

#### Rejected Applications.

Inventors who have rejected cases (prepared either by themselves or for them by other agents) and desire to ascertain their prospects of success by further efforts, are invited to avail themselves of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

Inventors doing business with us will be notified of the state of their application in the Patent Office whenever it is possible for us to furnish such information.

## A Great Repository of Practical and Scientific Information.

One of the Fullest, Freshest, and Most Valuable Hand-books of the Age. Indispensable to every practical man. Just Ready. Price, \$2.00, Free of Postage to any address in the world.

## THE Techno-Chemical Receipt Book:

Containing several thousand Receipts covering the Latest, Most Important, and Most Useful Discoveries in Chemical Technology, and their Practical Application in the Arts and the Industries. Edited chiefly from the German of Drs. Winkler, Elsner, Heintze, Mierzinski, Jacobsen, Koller, and Heinzeling, with additions by William T. Braunt, Graduate of the Royal Agricultural College of Eldena, Prussia, and William H. Wahl, Ph. D. (Heid.), Secretary of the Franklin Institute, Philadelphia; author of "Galvanoplastic Manipulations," illustrated by 78 engravings. One volume, over 500 pages, 12mo., elegantly bound in scarlet cloth, gilt, closely printed, containing an immense amount and a great variety of matter.

Price, \$2.00, free of postage to any address in the world.

**ABSTRACT OF CONTENTS:** Adulterations, Imitations, etc. How to Detect Them; Alloys; Artificial Gems, Pearls, and Turkish Beads; Bitters, Cordials, Elixirs, Liqueurs, Rafadins, and Essences, Extracts, Tinctures, and Waters Used in their Manufacture, and the Manner of Coloring them; Blasting Compounds, Blasting Powder, Dynamite, Gun Cotton, Gunpowder, Nitro-Glycerine, Fulminates, etc.; Bleaching; Boiler Incrustations; Bone, Horn, and Ivory to Bleach and Dye them, and make Imitations and Compositions; Bronzing and Coloring of Metals; Building Materials, Artificial Building Stone, Mortars, etc.; Cocoa and Chocolate; Celluloid, Caoutchouc, Gutta Percha, and Similar Compositions; Cements, Pastes and Putties; Chemical and Techno-Chemical Expedients, Preparations; Cleansing, Polishing, and Renovating Agents; Colored Chalks, Crayons, Pencils, and Inks for Marking Linen, etc.; Confectionery; Copying and Printing; Damaskeening Steel; Decoration, Ornamentation, etc.; Dentifrices and Mouth Washes; Dyeing Woolen and Cotton Goods, and Yarns, Silk, Straw Hats, Felt Hats, Kid Gloves, Horsehair, etc.; Mordants; Electro-Plating, Galvanoplasty, Gilding, Nickeling, Silvering, Tinning, etc.; Enamels and Enameling; Feathers, Ostrich, Marabouts, etc., how to Wash, Restore and Dye; Fire-extinguishing Agents and Means of Making Tissues; Wood, etc. Incombustible; Fireworks; Food and Food Preparations; Freezing Mixtures; Fruit and other Syrups; Fuel and Heating, Heat Insulation (Non-conducting coverings); Fusible Colors used in Porcelain Painting; Glass, Composition of the various kinds of, Colors for, and Processes for Enameling, Engraving, Gilding, Silvering, Pulverizing, Filling, Bending, etc. Glazes for Earthenware; Glass and other Signs; Glue, Manufacture of; Household and Rural Economy; Illuminating Materials; Imitations, Substitutes, etc.; Indigo, Indigotine, and Alizarine; Inks, Lithographic, Printing, and Writing; Jeweler's Foils; Lacquers and Varnishes; Leather, Tanning and Dyeing, including Furs, etc.; Liquors and Beverages: Beer, Brandy, Gin, Whisky, Wines, etc.; Lubricants for Machines, Wagons, etc.; Marine Glue; Matches; Metal Industry; Mustards; Oils and Fats, Animal, Vegetable, and Mineral; Oil Paintings; How to Cleanse, Pack, and Varnish them, and to Restore Gilt Work; Paints and Pigments. Grinding and Mixing Colors, Graining, Imitation of Marbles. Paints and Washes for Various Purposes, etc.; Paper and Paper Materials, Manufacture, Staining, etc.; Glass, Sand and Emery Paper; Perfumery, Aromatic Vinegars, Cosmetics, Extracts, Hair Oils, Pomades, Powders, Washes, Fumigating Articles, etc.; Pharmaceutical preparations; Photography; Plaster of Paris Casts which can be Washed; Preserving Meat, Milk, Vegetables, Vegetable Substances, Wood, etc., and Preservatives; Sealing Wax and Wafers; Sho-Blacking, Dressings, etc.; Sizing and Dressing for Cotton, Wool, Straw, etc.; Soap, Hard and Soft Soaps, Medicated and Toilet Soaps, etc.; Soldering and Solders; Sugars, Glucose, etc.; Textile Fabrics and Tissues; Tobacco, Smoking Tobacco, Snuff, Sternutative Powders, etc.; Vinegar, Manufacture of Ordinary and Fine Table Vinegars; Washing and Scouring, Manufacture of Washing Blue, etc.; Waste and Offal, Utilization of; Water-Glass (Soluble Glass) and its Uses; Water-proofing Compounds; Wax and Wax Preparations; Wood Gilding, Polishing, Staining, etc.; Yeasts, Manufacture of Pressed Yeasts, Bakers' and Brewers' Yeast, etc.; **Addenda.** Alloys; Antiseptic and Preservative Agents; Artificial Eyes, Manufacture of; Asbestos and its Uses; Bleaching; Bookbinding, Gilding, and Ornamenting; Bronzing, Gilding, Silvering, etc.; Building Materials, Celluloid, Imitations, Substitutes, etc.; Cement Work; Cleansing, Polishing, and Renovating Agents; Colors, Enamels, Cements, Glue, Varnishes, Water-proofing Substances, etc.; Copying; Explosive Agents; Glass; Horn Combs, Manufacture of; Lubricants, Blacking, etc.; Metal Industry; Miscellaneous; Oils and Fats; Paper; Straw, Bleaching and Dyeing of; Strength of Materials; Willow-Ware; Index.

A Circular of 32 pages, showing the full Table of Contents of this important book, sent by mail free of postage to any one in any part of the world who will furnish his Address.

**HENRY CAREY BAIRD & CO.,**  
Industrial Publishers, Booksellers & Importers, 810 Walnut Street, Philadelphia, Pennsylvania, U. S. A.

UNCLE Sam has found it at last! A sure remedy for Torpid Liver, Sick Headache, Habitual Constipation, Chills and Fever, and all affections of the Kidneys and Liver. This is a New Compound, and one trial will convince you that it is the Cheapest and Best Remedy in the Market for Diseases of Kidneys, Liver and Stomach. If you want a pure vegetable compound, that is positively guaranteed to contain no mercury, go to your Druggist, and get a Bottle of the Arkansaw Liver and Kidney Remedy. Price, \$1.00 per Bottle.

For Sale by all Druggists.

## ANNUAL MEETING.

The regular Annual Meeting of the Stockholders of the Golconda Mining Company will be held at the office of the company, No. 309 California street, rooms 3 and 4, San Francisco, California, on Monday, the twenty-third (23d) day of August, 1886, at the hour of 2 o'clock P. M., for the purpose of electing a Board of Directors to serve during the ensuing year, and the transaction of such other business as may come before the meeting. Transfer books will close on Friday, August 20, 1886, at 3 o'clock P. M.  
J. M. BUFFINGTON, Sec'y.  
Office—Rooms 3 and 4, No. 309 California Street, San Francisco, California.

## Books on Assaying.

By C. H. AARON.

## PART I.—Gold and Silver Ores.—Price \$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes thereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

## Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 12mo. pages, with illustrations, well bound in cloth. Price, \$1, postpaid. Sold by DEWEY & Co., Publishers, No. 252 Market street, San Francisco.

## PARTS II AND III.

**Lead, Copper, Tin, Mercury, etc.**

Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

## Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Manipulation, etc.; Lead Ores; Copper Ores; Volumetric Assays; Parting Process; Amalgamation; New Process; Preparation of Potassium Zanthate; Electrolytic Determination of Copper in Ores, etc.; Assaying of Tin Ores; Assaying of Mercury Ores; Assaying of Zinc Ores; Assaying of Zinc Ores, New Method; New Assay of Nickel and Cobalt; Assay of Chromium; Assay of Bismuth; Assay of Arsenic; Assay of Antimony; Assay of Sulphur; Assay of Salt; Appendix to Part I; Notes on Crucible Assays; Weighing by Oscillation; Appendix to Part III; The Assay of Lead; The Assay of Copper.

There are 160 12mo. pages with illustrations in the volume which is bound strongly in cloth. Price postpaid, \$1.75 Sold by DEWEY & Co., Publishers, No. 252 Market St., S. F.

## Testing and Working Silver Ores

An illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working samples, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride of lime, ammoniac, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles Smelting, Mexican process, Chilean process, Kroehnke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel sough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tallies, and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

Price, post free, \$2.00. Sold by DEWEY & Co., Publishers, 252 Market St.

## Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, coin, postage free. Sold by DEWEY & Co., Publishers, 252 Market St., San Francisco, Cal.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY & Co., S. F.

## Practical Treatise on Hydraulic Mining.

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For sale by DEWEY & Co., Publishers, 252 Market St., San Francisco.

## IMPORTANT TO GOLD MINERS! SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.

BEST SOFT LAKE SUPERIOR COPPER USED.

3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates. Old Mining Plates Bought, Replated, or Gold Separated.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 &amp; 655 Mission St., San Francisco.

E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR &amp; CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

## THE FRISBEE-LUCOP MILL,

## A CENTRIFUGAL ROLLER MILL

—FOR WET OR DRY—

Reduction of Ores, Quartz, Phosphate Rock, Carbon, or other Mineral Substance to any degree of fineness in a rapid and economical manner.

Any method of amalgamation may be applied.

At 300 revolutions per minute will pulverize 2000 pounds of quartz per hour to 60 mesh dry, and from 3000 to 6000 pounds wet.

All wearing parts easily and cheaply replaced. May be seen in operation at the New York Metallurgical Works, 104 and 106 Washington St., and Pacific Iron Works, San Francisco.

Certificates as to performance of the Mills, and any information required, furnished on application.

**IMPROVED FORM OF HYDRAULIC GIANTS.**

The above cut illustrates the **IMPROVED FORM OF HYDRAULIC GIANTS**, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. K. Hoskin et als.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,

39 to 51 Fremont St., San Francisco, Cal.

This cut represents our

**IMPROVED**  
**HYDRAULIC**  
**MACHINE.**

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List.

## Miscellaneous.

The chlorides of Jefferson, Nev., are taking out good ore.

A COMPANY in Stockton is about to bore wells in that city for natural gas.

QUICKSILVER is higher in price now than it has been for several years.

STOCKS of pig lead in New York July 1st amounted to 3,599,380 pounds.

It requires from two to four per cent more fuel to run furnaces in Leadville than in the valley.

LARGE deposits of oxide of antimony and silver are said to exist in Woodside Canyon, Nevada.

THE shipments from Silverton, Colorado, between January 1st and July 17th, numbered 6900 tons. The *Democrat* says the shipments for the balance of the year will average 100 tons per day.

THE River and Harbor bill has again been changed, the last change being a clause which directs the Secretary of War to bring suit against hydraulic miners to compel them to cease depositing tailings in navigable streams.

THE Copper Queen, the largest copper producer in Arizona, and a mine which has considerable influence on the price of copper in the United States, closed down on the 2d inst. on account of the very low price of copper. The closing is not permanent.

THE V-flume case is on trial in this city. The suit is for damages by the alleged infringement of a patent on the so-called V-flume, which is in use in several portions of California and Nevada. It is a test suit and affects a number of flume companies. The matter has been in litigation for years.

JAMES L. DE FREMERY, son of the banker of this city, has taken the highest honors at the University of Heidelberg. This university, which has just celebrated its 300th anniversary, is confounded by many with the Freiberg mining school, which is an entirely separate and distinct institution.

THE Gold Hill Company's 25-stamp mill, and the hoisting works at the company's mine—the Pioneer (in Idaho), have been destroyed by fire. The hoisting works at the Pioneer mine are not what is known as the Gold Hill hoisting works, being much lighter than the latter. The works will probably be rebuilt at once.

THE Los Angeles *Herald* says: There are many who do not know that the Calico district, in San Bernardino county, got its name from the variety of colors observed on the rocks. They are very pinto, as the Spanish has it. Perhaps a few years ago the place would have been called the "Dolly Varden."

THE Reno *Gazette* learns that the difficulties encountered by S. Wenban in establishing the new leaching works on his mine at Cortez have been overcome and he is now turning out large quantities of bullion. He shipped 50 bars last month weighing about 100 pounds apiece, and over 500 fine. He had to ship them by express instead of freight, which speaks well for their quality.

THE Flagstaff (A. T.) *Champion* says: A vein of free gold, six feet wide, has been struck in the Ruby mine, on the east slope of the Magdalena ridge in Socorro county, New Mexico, which has caused a rush of prospectors to that section, and claims have been taken up for miles around the mine in every direction. There is quite an excitement throughout that country, and rich finds are expected as the result of prospecting.

## Mining Share Market.

Very little is doing now in stocks, the course of mining development being rather slow on the Comstock just now. The 600-level of the Savage is showing better and more extensively in good ore, and the crosscuts on the 3200-level are cutting the vein of good ore found in the west face of the 3200 station of the Combination shaft, and which evidently extends northward. Yet the stock market shows a decline. It would seem that the better the prospect the worse are stocks.

Owing to work in the Crown Point and Belcher mines being suspended for repairs, etc., the payroll of the Comstock on the first of this month was a few thousand dollars less than usual, but that will be all right again in the course of a couple of weeks, when the repairs will be concluded and active mining work resumed as usual. The Yellow Jacket had a spur-wheel broken the first of the week, but a new one was promptly substituted and the work goes right straight along again as usual.

## Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this Coast now for so many years, the firm's name is a well known one. Another reason for its popularity is that a great proportion of the Pacific Coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this Coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That this is understood and appreciated, is evidenced by the number of patents issued through their *SCIENTIFIC PRESS* Patent Agency (S. F.) from week to week and year to year.

## Mining and Scientific Press.

THE BEST PRACTICAL MINING JOURNAL IN THE WORLD.

Established in 1860, this paper has been eminently successful as a popular and useful mining and mechanical journal. Relative to precious metals especially, it is the leading mining paper of the world.

It is largely patronized by the leading Miners, Mine Owners, Superintendents, Engineers, Metallurgists, Chemists, Manufacturers, Mechanics, Scientific, Professional and Industrial "Men of Progress" on the Pacific Coast and many leading Mining Men throughout the mining fields of the world.

It is by far the best advertising medium in the Pacific States and Territories for Mining, Mechanical, Engineering, Building and Manufacturing Tools and Implements Goods, Supplies, etc.

Being thoroughly able and reliable in its editorial and business management, and long established in the most progressive industrial portion of the Union, at present, its power as an advertising medium is unsurpassed.

Subscription, \$3 a year. Advertising rates, moderate. Send for samples and further information.

DEWEY & CO., Publishers,

## New York Metal Market.

Telegraphic advices dated August 11th give the following New York prices:

BORAX—6 1/2 @ 7 1/4 c.  
BAR SILVER—9 1/4 per oz.  
COPPER-LAKE—\$10.12 1/2 @ 10.25.  
IRON—No. 1, \$17.00 @ 18.00; No. 2, \$15.00 @ 16.00.  
LEAD—\$4.85 @ 4.95.  
QUICKSILVER—43 @ 43 1/2 c. per lb.

The following is the latest by mail from the "New York Metal Exchange Market Report":

COPPER—Quiet but steady; Lake offered at 10.20c. Transferable Notices (Lake) offered at 10.20; Transferable Notices (Chili Bars) offered at 4.39.

LEAD—Nominal at 4.80c. Transferable Notices (Domestic) issued at 4.80.

TIN—Steady, closing at \$21.65 @ 21.70. Transferable Notices issued at \$21.75c.

SILVER—New York, 91 1/4 per oz. London, 42d. MAKER'S PRICES—At tidewater. 100 ton lots of listed irons (when brand is specified) range nominally about as follows: Lehigh, Grade No. 1, \$18 @ 18.50; No. 2, \$17.00 @ 17.50; Grey Forge, \$15.00 @ 16.00. Hudson River, Grade No. 1, \$18 @ 18.50; No. 2, \$17.00 @ 17.50; Grey Forge, \$15.00 @ 16.00. Southern, Grade No. 1, \$18.00 @ 18.50; No. 2, \$17 @ 17.50; Grey Forge, \$15 @ 16.

Prices generally ruling for metals not regularly dealt in on call at the N. Y. Exchange, covering extremes of buyers' and sellers' views. All prompt delivery.—Australian Tin, \$21.80 @ 22.00; Billiton Tin, \$21.90 @ 22.50; Banca Tin, \$22.40 @ 22.80; Baltimore Copper, \$9.25 @ 9.40; Orford Copper, \$9.25 @ 9.40; P. S. C. Copper, \$9.25 @ 9.40; Foreign Lead, \$4.80 @ 4.90; Foreign Spelter, \$4.80 @ 4.85.

ALL misfits, ocularly demonstrated errors of refraction, carefully diagnosed. C. Muller, the leading optician, 135 Montgomery street. x

## Inducements to Subscribers.

To favor subscribers to this paper, and to induce new patrons to try our publication, we will furnish, to those who pay fully one year in advance of date, if requested, the following articles (while this notice continues) at the very greatly reduced figures named at the right:

- 2.—World's Encyclopedia, 794 pages, 1200 illustrations (exceedingly valuable).....\$0.50
- 3.—Dewey's Patent Elastic Binder (cloth cover), name of this paper stamped in gilt..... .50
- 6.—To New Subscribers, 12 select back Nos. of this paper.....Free
- 7.—Any of Harper's, Frank Leslie's and most other first-class U. S. periodicals, 15 per ct. off regular rates.
- 9.—Pacific Coast and Eastern Bibles, Books and Periodicals, except special publications, we can usually give 10 to 15 per cent off advertised retail rates.
- 10.—Picturesque Arizona, 380 pages, in cloth and gilt. .25
- 11.—Californian, 100 pages, Magazine, 1880 to 1882 (3 Vols.) single Nos..... .03
- Per volume, unbound, 5 Vols..... .20
- Per volume, bound, cloth back and stiff paper sides, about 600 pages. (Send two-cent stamp for sample)..... .40
- 14.—Dewey's Pat. Newspaper Fileholder (18 to 36 in.) .25
- 15.—Life among the Apaches, 322 pages, stiff cloth. .25
- 17.—Architecture Simplified, 60 pages..... .15
- Webster's Dictionary, 634 pages, with 1500 illustrations; very handy and reliable..... .50
- De Groot's History of Mining in California, 16 pages. .05
- Beautiful Poetic Review, entertaining and instructive, 35 pages (a handsome and pleasing present)..... .25

NOTE.—The cash must accompany all orders. Address this office, No. 252 Market St., S. F.

Send for any further information desired. Inform your neighbors about our offers and paper. Sample copies of this paper mailed free to persons thought likely to subscribe.

## List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in DEWEY & Co.'s Patent Office Library, 252 Market St., S. F.

FOR WEEK ENDING AUGUST 3, 1886.

- 346,716.—ANTI-FRICTION BEARING—L. W. Boyer, S. F.  
346,473.—WASHING MACHINE—Gooch & Olsen, Bellingham, W. I.  
346,547.—PORTABLE BOOK-HOLDER—Mary J. Holt, S. F.  
346,589.—WHIFFLETREE CLIP—G. C. Johnson, Fort Bragg, Cal.  
346,590.—WHIFFLETREE HOOK—G. C. Johnson, Fort Bragg, Cal.  
346,766.—GANG-PLOW—E. H. Nicholson, Santa Maria, Cal.  
346,682.—BOOT-JACK—Wm. Quinlan, Punta Arenas, Cal.  
346,776.—BOOT-PROTECTOR—L. C. Rodenberger, Medford, Ogn.  
346,624.—VEHICLE SHAFT—W. L. Walker, Brooks, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

## Practical Hydraulics.

By P. M. RANDALL.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

## Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:  
General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulas Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated, and Expressed in Formula and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water Over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow Through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water Through Short Tubes and Compound Tubes; Flow of Water Through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow Through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by DEWEY & Co., Publishers, 252 Market St., San Francisco.

## Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

## Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

## FRESNO COUNTY.

## BRIGGS' SELMA TRACT.

## THIS COLONY

Has been subdivided into 20-acre lots with convenient **ROADS AND DITCHES** on the land.

Situated 1½ miles N. W. of **SELMA** (a fast-growing Railroad town 15 miles S. W. of Fresno and the second in the County) and 2 miles S. of Fowler, also a Railroad town.

IT IS FIRST-CLASS

**Fruit,  
Vine, and  
Alfalfa  
Land,**

Some of it being specially adapted to Gardening. It has

## SUPERIOR WATER PRIVILEGES,

Having a main Canal 60 feet on the bottom, running through the land and all necessary main distributing ditches, making it a very desirable location for a Colony, as its

## WATER AND RAILROAD FACILITIES

Cannot be surpassed in the County.

**TO BE SOLD CHEAP,  
AND ON EXTREMELY EASY TERMS TO ACTUAL SETTLERS.**

## HOME SEEKERS!

DON'T MISS THIS OPPORTUNITY!

Correspondence solicited and lands shown free of charge.

L. SHARPE, Selma, Cal., or O. J. WOODWARD, Fresno, Cal.

## THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

## GIANT POWDER or DYNAMITE,

Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and  
GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.

## JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blast-  
ing Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and  
saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

## BANDMANN, NIELSEN &amp; CO.,

CAPS and FUSE for Sale.

GENERAL AGENTS, SAN FRANCISCO, CAL.

A. T. DEWEY. } Dewey & Co.'s Scientific Press Patent Agency { ESTABLISHED  
W. B. EWER. }  
GEO. H. STRONG. } 1860.

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class  
Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal  
nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original  
cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies.  
The information accumulated through long and careful practice before the Office, and the frequent examination of  
Patents already granted, for the purpose of determining the patentability of inventions brought before us, enabled  
us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not  
few. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

THE CONSUMERS' COMPANY.  
VULCAN B B AND AJAX.

The Best LOW GRADE EXPLOSIVES in the Market.  
SUPERIOR TO BLACK OR JUDSON POWDER.

Vulcan Nos. 1, 2 and 3,

The Best NITRO-GLYCERINE POWDERS Manufactured.

## THE ROLLER ORE FEEDER

[Patented May 28, 1882.]

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required. In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repairs.

Established 1856.

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.  
Extra sizes and lengths made to order on short notice.

**TUBBS & CO.**

611 and 613 Front St., San Francisco

## HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

**BALFOUR, GUTHRIE & CO.,**

316 California St., San Francisco.

## FULTON IRON WORKS,

all kinds of  
Chemical Stoneware  
—FOR—  
Manufacturing  
Chemists.  
Also Chemical Brick  
for Glover Tower.

### INVENTORS, TAKE NOTICE

**L. PETERSON, MODEL MAKER,**

258 Market St., N. E. cor. Front (up stairs), San Francisco  
Experimental machinery and all kinds of metal, tin  
and Brasswork.

# \$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,  
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS**  
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street.

SAN FRANCISCO, CAL.

# \$1,000 CHALLENGE ACCEPTED, PRICE, FIVE HUNDRED AND FIFTY DOLLARS

(\$550.00).

**THE  
"TRIUMPH" ORE CONCENTRATOR.**

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE, placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

JOSHUA HENDY MACHINE WORKS,

Nos. 39 to 51 Fremont St.,

San Francisco, Cal.

1850. 1835.  
**RANKIN, BRAYTON & CO.,**  
BUILDERS OF  
**MINING MACHINERY.**

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING and REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

## WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves ALL THE AMALGAM GOLD and SILVER that ESCAPES THE BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

## BAKER'S MINING HORSE POWER.

Possessing ALL THE REQUIREMENTS of a FIRST-CLASS HOIST, and affording means for the CONTINUOUS OPERATION of a BLOWER, WITHOUT interfering with the HOISTING APPARATUS. It is made ENTIRELY OF IRON, no piece WEIGHS OVER 300 POUNDS. At the ORDINARY SPEED of a horse, a 700-pound BUCKET OF ORE may be raised 75 feet per minute. The HOISTING-DRUM is under the COMPLETE CONTROL of the man of the shaft, and is CAPABLE OF CARRYING 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

## PATENT LIFE-SAVING RESPIRATOR

Entirely Prevents Lead Poisoning  
and Salivation

The most perfect appliance for people engaged in Smelting, Dry Crushing, Guano Works, Quicksilver Mines, Lead Corroding, Threshing and Stock-driving, and all other occupations where there is dust, poisonous vapor, or bad odor.

In Feeding Threshing Machines, and similar work, they are indispensable, as no foreign substances can be inhaled when they are worn.

The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3.00 each or \$30.00 per dozen. Sent post-paid to any address on receipt of price.

Address communications and orders to

T. B. JEWELL, Sole Agent,  
330 Pine St. (Room 4) San Francisco.

Send for Descriptive Circulars containing Testimonials of well-known parties who are at present using them.

## THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

## Head Waters of the Snake.

In a recent interview our traveling representative gleaned the following items, of a prospecting trip in Wyoming to the head waters of Snake river, from K. P. Plowman, one of Idaho City's "placer kings." "Yes, I have been up to the head waters of the Snake, and I think it the finest country that ever laid out-doors," said Mr. P. in answer to a question. "In July, 1885," he continued, "a party of seven of us from Boise county, fully equipped for prospecting with a two months' supply of grub, started to investigate that country, leaving the Utah Northern at Market lake. Traveling through the Teton basin, a quasi-valley fairly timbered extending along Perry's river and covering a scope of country about 14x60 miles, we crossed the Teton mountains by the only available pass (during the summer months) into a valley and foothill country on the south fork of the Snake, known as the Jackson basin. The source of the Snake is a beautiful lake at the upper or northern end of the basin, known as Jackson lake. This body of water is a superb one, and for sublimity and picturesque beauty cannot be excelled. It is about 15 miles wide by 30 miles long, and as clear and placid as a polished cut-glass mirror. The background of shrubbery, towering pines and snow-capped peaks extending from the water's edge toward and against the scattering clouds, and reflected in its crystal depths, makes a scene worthy of the painter's brush, and worth a season's cleanup. The 'Reptile,' as some designate the Snake, is nearly 600 feet wide at its source, the lake, and its course toward the Columbia entitles it to a name that would indicate a serpentine course. The formation is cement gravel until the lake is reached. The river bars prospected well; some went 30 colors to the shovel. Above Lake Jackson no prospects were found worth noting. Twenty miles below the head of the Snake we prospected a distance up on the Grosventre river, which resulted in our locating several claims. This river has considerable fall, and water can easily be made to cover the bars. Owing to having no lumber, nor machinery with which to cut any, we were unable to do any sluicing. No quartz float was noticeable on the entire trip. We prospected the Snake a distance of nearly 200 miles. The advantages enjoyed by mining men in that region are unsurpassed. Why that great basin of good agricultural, stock-grazing and mineral lands has not been settled up ere this I cannot imagine. Some of us will more than likely go back this season and look after our placers. Should matters shape themselves so as to demonstrate the mining interests to be worthy of mention, the MINING AND SCIENTIFIC PRESS will hear from us." The best route for prospectors reaching this new field is via the Oregon Short Line and Utah Northern.

IF TWO persons agree with the third to furnish necessary supplies to the latter, as the same shall be required, for discovering and locating lodes for the joint benefit of all, the latter may treat this a condition precedent, and upon failure to furnish the supplies he may abandon the enterprise, or he may proceed to discover and locate lodes in his own right, without regard to the contract.

SILVER.—On Wednesday 100,000 ounces of crude silver sold in this city at 90½ cents per ounce; and 100,000 ounces of refined at 90¼ to 90½ cents.

## Foundry Notes.

The Risdon Iron Works have shipped two large air-compressors to the Empire mine, Grass Valley.

The Fulton Iron Works have about completed the large dredger to be used by the Government in dredging the mines. They will shortly commence work on the engines and boilers for the ferry steamer of the South Pacific Coast R. R. Co.

The difficulties between the strikers and the

Vertical Section Through Slag-lip.

WATER JACKET COPPER FURNACE.

Union Iron Works have not yet been settled.

The Pacific Rolling Mills are now very busy on orders, keeping employed a full force of men. The roadbed of the Broadway cable road, Oakland, is completed. The Mill Co. now make a specialty of cable railroad construction.

The Pacific Iron Works have been turning out the usual amount of work. Among the recent shipments may be mentioned: Another 40-ton smelting plant for the Selby Smelting Works; a 10 stamp silver mill for the San Antonio Company in Mexico; a 40-ton gold mill, with six Duncan concentrators, for the Golden Eagle Company; a 100-ton gold mill for the Quartz Hill Company; a set of hoisting works for the North Star mine, together with an equipment of Duncan concentrators for the mill; a concentrating plant for the Gypsy Queen Company of New Mexico; several Duncan concentrators have also been recently shipped to various mines in Central and South America, as well as the various Australian colonies, Japan, etc.

It is said that electricity is going to be used in the process for working Meadow Lake ore.

## Water-jacket Furnaces.

The engravings on this page show the construction of the water-jacket furnaces used on this coast for the smelting of oxidized and other copper ores. They consist simply of a casing, B, with an outer and inner shell of iron, between which water freely circulates. Some 25 to 30 gallons of water are required per minute for this purpose. The inlet of the water is through the pipes F; the outlet is through G. Hand-holes, E, in the bottom of

Horizontal Section Through Tuyeres.

Bottom Plate.

this space, are arranged to permit ready access for cleaning. Most western water contains lime, and the water-space of the water-jacket scales almost as rapidly as a boiler, thus making these hand-holes imperative.

The blast is carried around the furnace in the circular casing C, and enters through the tuyeres D. Opposite each tuyere there is a hand-hole (and an eye-hole) in this casing which permits ready access to the interior of the furnace. The outer shell of the furnace is continued down some distance below the water-jacket and there forms the casing of the crucible.

The interior of the crucibles is lined with fire-brick and clay, M. This clay bottom of the crucible rests on the hinged iron doors, P, which can be dropped at any moment, when the furnace is blown out, to remove accretions in the crucible, or for any other purpose. The slag lip L, attached to the shell of the furnace, carries off the cinder. The tapping-notch, O, is used for tapping the metal produced. The whole furnace stands on four iron pillars, R, and is covered by the hood, H, leading to the stack, K. The hood, H, has a charging-door

cut in it. The level of the charge is generally kept a foot below the bottom of this charging-door.

A furnace of this class, 42 inches in diameter at the tuyeres, and 9 feet high, driven by a No. 4½ Baker blower, run 100 to 120 revolutions per minute, will readily smelt 40 tons of ore per day. With an increased amount of blast, an average of 50 tons has been smelted in these furnaces, and even 60 tons have been put through; but the experience at Globe and elsewhere has proved that this forced rate of smelting leads to an increased loss of copper in the slag and is not economical. Excellent smelting can be done in these furnaces when the rate of smelting is not pushed much above 40 tons per day. The charging of these furnaces is done, like that of an iron furnace, in horizontal layers, charges of coke, ore, and the necessary fluxes alternating in regular order.

## Our Sunstrokes.

The occurrence of three cases of sunstroke on a single day in July in California, where such unfortunate phenomena are exceedingly rare, has given rise to much discussion among meteorologists and physicians. The ingenious in matters of theory have done their best to explain this singular outcropping. According to the monthly circular of Dr. Tyrrell, Secretary of the State Board of Health, there was one death from "thermic fever" in Sacramento, in the person of a man who, in the army, had had a sunstroke years before. The second case occurred in Oroville, in the practice of Dr. J. H. M. Karsner, who reports that the man, aged 36 years, had walked a mile in the sun, and on returning home lay down in the cellar, complained of great heat and thirst, became unconscious, and died in two hours after seizure.

The third case is reported by Dr. A. P. Tartar, of Tehama, in the person of a man aged 72 years, of temperate habits. He was a bridge-tender, and obliged every morning to inspect the bridge as the trains passed over. As he was making this inspection he was stricken down on the bridge, and when found conveyed to his home, where he soon became unconscious and died in about two hours. Dr. Tartar is of the opinion that the unusual moisture in the ground from the abundant and late rains of winter had produced that degree of humidity in the atmosphere which makes sunstroke possible. He remarks that sloughs and ponds usually dry at this season are still holding water, and their evaporation must add something to the cause.

This idea seems reasonable enough, for the most obvious difference between our conditions and those at the East is that we have dry-heated air and they humid. It would seem, however, that if the air be so changed by heavy rainfall in winter, or large supply in sloughs, etc., it could also be thus affected by evaporation from extensive irrigated areas. Such does not, however, appear to be the case, for there are regions where the ground has become so overcharged with water that tule grows in low places, and water can be had in wells at a depth of four feet or so, and yet no case of sunstroke has been reported. In short, though there is the strongest testimony that drainage must be had to take off the surplus water or else much of the country would be swamped, there is still no dangerous humidity in the air. It seems to us that the matter must be further investigated.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eps.

## Can Lode Mining be Studied as a Business?

[Written for the Press.]

The query which I use as a heading is suggested by the well-known fact that Eastern capitalists who invest in mining claims on the Pacific Coast regard it as a matter of no importance whether their local manager is or is not possessed of mining experience. Under the evident belief that any man can "run" a mine, they send out incompetent light-weight creatures as their superintendents, and when these fail in returning dividends, the blame is laid on the mining ground and not on the management. So common have failures become from that cause, and the unskillful selection of properties to be handled, that Western mining is now regarded in Eastern cities as a sort of lottery, in which little else than blanks are drawn. The farmer who, without suitable training, embarks heavily in commercial city business, soon descends to his own level, and goes back to the country a wiser and poorer man. The court practice of the lawyer does not give him instruction in the growing of pumpkins, nor does the using of chisels teach a carpenter how to shoe mules. The large dry-goods merchant does not want a farm laborer as a clerk, and yet he has often by his vote aided in selecting mining superintendents on no more tangible grounds. I believe the query which forms the caption to this letter can be answered in the affirmative. As a business, mining requires close observation of "indications," patient investigation of natural laws by which it is affected, great administrative ability, and persevering, vigorous application on established and approved lines of action. The skillful miner must be ready to meet changes in his surroundings at any moment. If, with increased depth, his decomposed surface ores become refractory sulphurets, he ought to know what to do in order to extract their metal. A "tender-foot" superintendent is puzzled in such a case, and the property under his care is depreciated, if not even abandoned.

## What Old Miners Have Learned.

Thirty years ago very few men on the Pacific Coast possessed practical mining skill. All were learners, and, when the Comstock was discovered, that became the great training school for the whole country. So late as 1863 it was only necessary to concentrate a little of the muddy water below the Gold Hill quartz mills to understand how much there was still to learn ere mining and milling would go hand in hand in saving the precious metals.

The sulphurets running to waste daily were worth thousands of dollars, and at the mines a lack of assortment, and a general belief that the available ores were inexhaustible, led to careless management. The streets of Virginia City were at one point made solid and smooth by quartz which now would pay well at the mills. Out of these crude mining and milling practices has come the skillful treatment of all kinds of ores for which our Western States and Territories are justly acquiring fame over the whole world.

We are practically only at the beginning of our career in that direction, and a vast unknown field has still to be brought under control. The prospectors who branched out from the Comstock in early times and found new mineral belts and qualities of ore, forced our foundry and ore-reduction men into new lines of investigation. Such pioneers going from one camp to another, and if they found nothing to suit them, traveling for years through States and Territories, learned a great deal in their progress. If they failed to learn it was because they did not possess discriminating ability.

If they were observant they discovered the fact that paying, valuable mines had always certain geological environments. Either they were contact veins between two favorable formations, or were in a kindly primitive or metamorphic rock, in which ore bodies could live. On the other hand they learned, often by costly experience, that deposits of ore in hard limestone apart from any other formation, were not to be depended upon. They found that streaks of ore resembling veins in trachytic porphyry, or in slates where they followed the cleavage, would prove uncertain in depth. With years of observation and much labor, those of them who read while they pondered came after a time to be able to recognize a mine when they saw it, even if unopened. If they examined a quartzite reef, such as a California millionaire paid a large price for, because it showed rich surface ore, they were able to laugh at his "greenness" and decide that his reputation as a miner was anything but sustained by that stupid investment. The intelligent explorer and mine-owner is still prosecuting his educational researches. If he is stationary he falls behind his compeers in a very discouraging way. If he is not aware of this he is in no condition to keep in the van of his calling. In 10 years from now even the silly investors in mining claims from Eastern States may be led to admit that the miner, as well as the grocer, can

learn some things in his business that other persons could not be expected to know.

## The Science of Metallurgy

Must advance, side by side, with the practice of mining, if we, as a mining community, are to make the greatest possible progress. If the successful lode miner does not himself possess scientific knowledge, he ought to welcome it from afar as his coadjutor, and pay for it with a liberal hand. This, no doubt, will come to be a general custom in the future, and hence pre-eminent scientific ability and knowledge will everywhere deservedly command an encouraging premium.

There is a wider field for the scientist, who is ambitious to unlock Nature's secrets, than for the miner; but the latter has still a wide enough domain to more than exhaust his capacity for patient research, if he will but enter upon it with discretion and zeal.

## What Miners Learn by Blunders.

A good many years ago a silver lode reputed to be of great promise was offered to a mining man at \$10,000. He sent a half-educated expert to examine it, and later on his old foreman, and both reported favorably. He saw it himself, and could not fail to admit that for several hundred feet along its course it showed rich ore three to four feet wide. He wanted to do some work on it, but that privilege was denied. He finally bought it and after spending \$14,000 in labor, got out 40 tons of ore that assayed about \$40 per ton.

Away back in the long departed ages, nature painted a mineral lode that in the 19th century was to bamboozle and financially cripple a particular man.

It was a trap so skillfully baited that its real nature could only be detected, without labor, by the aid of previously acquired experience. The bait, in the form of ore, was neatly plastered along the surface about half an inch in thickness, and all beneath was nothing but a barren flinty quartzite. The deception was complete, but never again can the victim be lured into a similar blunder. Too little mining knowledge in his case was found to be a "dangerous thing." With his failure came the sneering insinuations from local newspapers which were common in such cases—"We knew it would end in this way," "Just as might have been expected from the man." Only a few months before these same newspapers had praised the buyer of the painted ledge for his far-seeing wisdom in securing the property ere it became widely known. In those early days small mining communities who singly and in groups had traveled hundreds of miles over sandy deserts to make "a raise" were naturally more liable to blame persons than mines if failure came to a camp.

Fortunately, in our better-informed times, editors of local newspapers display wisdom and judgment such as our pioneer journalists did not possess. The trans-desert adventurers of our day have learned by experience, too, that it is only in rare instances that mountains surrender their mineral treasures without a long and vigorous siege in which brains, money and hands must unitedly engage.

CENDA.

## The Lower Springs Mines.

EDITORS PRESS:—Please give space in your valuable columns for a few remarks relative to this forsaken but not forgotten camp. There are now very few miners, but those that are left are striving hard to show to the public that there are good mines here. There appears to be considerable excitement in the surrounding mining camps, but few people care anything about Lower Springs mines because so many different parties have failed to accomplish anything in milling or mining.

The Elizabeth Longly mine, better known as the Muchmore mine, is the most promising one yet discovered in this part of California. It has a tunnel run upon the ledge a distance of 150 feet, showing excellent ore all the way, and a well-defined large ledge with talc-slate formation on the hanging wall. This ledge runs east and west, pitching north at angle of 40 degrees. They also have an incline down 70 feet upon the ledge, 30 feet of which is below the tunnel level. This gives them a large body of stopping ground. The pay shoot of the richest rock is 100 feet wide, extending to the depth obtained, and is, I believe, the grandest prospect for a big mine in Northern California.

The Muchmore mine was condemned by two different parties, and was sold by the second party to Muchmore for \$20. The Muchmore Bros. possess great energy and faith in their mines and the camp in general. They are great workers, honest to themselves and their fellow-miners. All this makes them good men for building up a lost camp.

Mr. White, of the White Oak and Eastern Star mines, is laboring earnestly toward holding on to his three claims, hoping for better times.

## Rockford and Hargrave Mines.

The Rockford, better known as the Jones mine, is having an incline sunk upon the ledge just west of the old workings which was done many years ago, and is panning out very fine prospects. This mine was famous among the rich prospects of early days.

The Hargrave mine has a shaft upon the ledge 35 feet, shows some very fine milling ore, and is a very large ledge.

J. C. F.

Lower Springs, Shasta Co., Cal., Aug. 10th.

## The Miner's Ten Commandments.

Looking through an old scrap-book a few days since, says the *Cœur d'Alene Record*, we found an illustrated copy on blue paper of the "Miner's Ten Commandments," sent from California 36 years ago by Hiram Aikens to his family in Vermont. Even in these days they will well repay perusal. It is possible that there are old-timers who read them in 1849 or '50. The reader's imagination must supply the illustrations.

I. Thou shalt have no other claim than one.  
II. Thou shalt not make unto thyself any false claim, nor any likeness to a mean man by jumping one; whatever thou findest on the top above, or on the rock beneath, or in a crevice underneath the rock—or I will visit the miners around to invite them on my side; and when they decide against thee, thou shalt take thy pick and thy pan, thy shovel and thy blankets, with all that thou hast, and "go prospecting" to seek good diggings; but thou shalt find none. Then, when thou hast returned in sorrow shalt thou find that thine old claim is worked out, and yet no pile made thee to hide in the ground or in an old boot beneath thy bunk, or in buckskin or bottle underneath thy cabin, but hast paid all that was in thy purse away, worn out thy boots and thy garments, so that there is nothing good about them but the pockets; and at last thou shalt hire thy body out to make thy board and save thy bacon.

III. Thou shalt not go prospecting before thy claim gives out. Neither shalt thou take thy money, nor thy gold dust, nor thy good name, to the gaming table in vain; for 21, faro, poker, etc., will prove to thee that the more thou puttest down the less thou shalt take up; and when thou thinkest of the wife and children, thou shalt not hold thyself guiltless, but—insane.

IV. Thou shalt not remember what thy friends do at home on the Sabbath day, lest the remembrance may not compare favorably with what thou doest here. Six days thou mayest dig or pick all that thy body can stand under, but the other day is Sunday; yet thou wastest all thy dirty shirts, darrest all thy stockings, mend thy clothing, chop thy whole week's firewood, make up and bake thy bread, and boil thy pork and beans, that thou wait not when thou returnest from thy long-tom, weary. For in six days' labor canst thou not work enough to wear out thy body in two years; but if thou workest hard on Sunday also, thou canst do it in six months, and thou, and thy son, and thy daughter, thy male friend and thy female friend, thy morals and thy conscience, be none the better for it, but reproach thee, shouldst thou ever return with thy worn-out body to thy mother's fireside.

V. Thou shalt not think more of all thy gold, and how thou canst make it fastest, than how thou wilt enjoy it after thou hast ridden rough-shod over thy good old parents' precepts and examples, that thou mayest have nothing to reproach and sting thee when thou art left alone in the land where thy father's blessing and thy mother's love hath sent thee.

VI. Thou shalt not kill thy body by working in the rain, even though thou shalt make enough to buy physic and attendance with. Neither shalt thou kill thy neighbor's body in a duel, for by "keeping cool" thou canst save his life and thy conscience. Neither shalt thou destroy thyself by getting "tight," nor "high," nor "corned," nor "half-seas-over," by drinking smoothly down "brandy slings," "gin cocktails," etc. Neither shalt thou suck "mint-juleps" nor "sherry cobbles" through a straw, nor gurgle from a bottle the "raw material," nor "take it neat" from a decanter, for while thou art swallowing down thy purse, and thy coat from off thy back, thou art burning the coat from off thy stomach, and if thou couldst see the houses and lands, and gold-dust, and home comforts clearly lying there—"a huge pile"—thou shouldst feel a choking in thy throat; and when to that thou addest thy crooked walkings, and hiccuping talkings, of lodgings in the gutter and broilings in the sun, of prospect holes half full of water, and of shafts and ditches, from which thou hast emerged like a drowning rat, thou wilt feel disgusted with thyself and inquire: "Is thy servant a dog that he will do these things?" Verily I will say, Farewell, old bottle; I will kiss thy gurgling lips no more. And thou, slings, cocktails, punches, toddies and juleps, forever farewell. Thy remembrance shames me; henceforth "I cut thy acquaintance," and headaches, tremblings, heart-burnings, blue-devils, and all the unholy catalogue of evils that follow in thy train.

VII. Thou shalt not grow discouraged, nor think of going home before thou hast made thy "pile," because thou hast not "struck a lead," nor found a "rich crevice," nor sunk a hole upon a "pocket," lest in going home thou shalt leave four dollars a day, and go to work, ashamed, at 50 cents, and serve thee right; for thou knowest by staying here thou mightest strike a lead and \$50 a day, and keep thy manly self-respect, and then go home with enough to make thyself and others happy.

VIII. Thou shalt not steal a pick, or a shovel, or a pan, from thy fellow-miner; nor take away his tools without his leave; nor borrow those he cannot spare, nor return them broken, nor trouble him to fetch them back again; nor talk with him while his water rent is running on; nor remove his stake to enlarge thy claim; nor undermine his bank in following

a lead, nor pan out gold from his "rifle-box," nor wash the "tailings" from his sluice's mouth. Neither shalt thou pick out specimens from the company's pan to put them in thy mouth, or in thy purse; nor cheat thy partner of his share; nor steal from thy cabin-mate his gold-dust to add to thine.

IX. Thou shalt not tell any false tales about "gold diggings in the mountains" to thy neighbor, that thou mayest benefit a friend who hath mules, and provisions, and tools, and blankets he cannot sell—lest in deceiving thy neighbor, when he returneth through the snow, with naught save his rifle, he present thee with the contents thereof.

X. Thou shalt not commit unsuitable matrimony, nor covet "single-blessedness" nor forget absent maidens, nor neglect thy "first love;" but thou shalt consider how faithfully and patiently she awaiteth thy return; yea, and covereth each epistle that thou sendest with kisses of kindly welcome—until she hath thyself. Neither shalt thou covet thy neighbor's wife, nor trifle with the affections of his daughter; yet if thy heart be free, and thou love and covet each other, thou shalt "pop the question" like a man, lest another more manly than thou art should step in before thee, and thou love her in vain, and in the anguish of thy heart's disappointment thou shalt quote the language of the great, and say, "such is life," and thy future lot be that of a poor, lonely, despised and comfortless bachelor.

A new Commandment give I unto thee—if thou hast a wife and little ones that thou lovest dearer than thy life—that thou keep them continually before thee, to cheer and urge thee onward until thou canst say, "I have enough—God bless them—I will return." Then, as thou journeyest toward thy much-loved home, with open arms shall they come forth to welcome thee, and falling upon thy neck, weep tears of unutterable joy that thou art come; then, in the fullness of thy heart's gratitude, thou shalt kneel before thy Heavenly Father together to thank Him for thy safe return. Amen—so mote it be!

## Oseola District, Nevada.

This district is situated on the western slope of the Snake range of mountains, in White Pine county, Nevada, at the northern base of Jeff. Davis peak, which rises 13,300 feet above the ocean, and is 120 miles southeast of Eureka, the terminus of the Eureka & Palisade Railroad, and 93 miles west of Frisco, the terminus of the Utah Southern Railroad. It is connected with both railroads by a good wagon road, over which the heaviest machinery can be transported at all seasons of the year. With Eureka the district has a tri-weekly connection via the White Pine Stage Co.'s coaches, carrying the U. S. mails and Wells, Fargo & Co.'s express, and with Frisco it has a semi-weekly connection via Beers' Stage Line, carrying Pacific express. The altitude of the district is 7400 feet above sea level.

The geographical situation of the district renders it a "competitive point" as between the different railroads, and freights are cheaper than to any other point in Nevada. Snake valley, 18 miles to the east, and Spring valley, lying immediately under the district, two of the most prolific valleys in the State, produce an overabundance of hay, grain and all kinds of vegetables and small fruits, which are sold at cheaper rates than the same products command in California.

The geological formation is slate, quartzite and limestone, the slate lying near the base of the mountain, quartzite overlying the slate, and limestone capping the whole. The district is deeply indented by a bold gulch or ravine, which heads near the center of the mineral belt and flows thence three-fourths of a mile in a northerly direction; thence making a short curve it flows westerly for a distance of three miles and discharges into Spring valley. Along the bed and bars of this gulch and its short tributaries are immense deposits of auriferous gravel, varying in depth from 10 to 200 feet. From these gravel beds and deposits there has been taken, during the last ten years, by the most simple process (that of the common '49 rocker), over one-half million dollars in gold-dust. The gold-dust thus obtained is what might justly be termed coarse gold, the grains or nuggets varying in value from a few cents to as many thousands of dollars. One nugget found in the sand near the surface of the gulch contained over \$6000, and with it is connected a very romantic history. All the grains or nuggets of gold have more or less quartz adhering to them, and this quartz is identical with that found in the ledges and veins on the hillsides above.

Four miles from the above mines, on the edge of Spring valley, is an abundance of water for milling purposes by steam power. The water will have to be raised with pumps to a height of 20 feet. Wood can be obtained in abundance delivered at the mill for \$3 per cord.—*White Pine News*.

OIL YIELD OF SOUTHERN CALIFORNIA.—The production of oil in the Adams and Santa Paula canyons aggregates 250 barrels per day, and the Sespe 50 barrels. The production in La Puente and Petrolia amounts to 160 barrels daily. San Fernando turns out about 650 barrels per day. The aggregate, 1110 barrels per day in this part of the State, is a good beginning, but is a small affair compared with the 10,000 barrels that will be obtained in a short time.—*Los Angeles Herald*.

### The Great Question of the Day.

The country still continues in the throes of the great question of labor. There is no other theme before the people of such magnitude—none which involves such varied and important interests. But the really dangerous feature of violence, with which the issue was first inaugurated, has passed comparatively out of sight, and has been relegated to the place where it belongs—to a few banded and imported anarchists—men who have no interests in common with labor; men who are the enemies of all labor and all progress save that upon the downward way to desolation and ruin. The honest and intelligent workmen of this country know that violence is not an American remedy. They know that here the workingman may become the employer of next year, and they know that such advancement can be brought about only by industry, sobriety and peace.

Since our last issue strikes have become more emphatic in this city, and it is to be regretted that one instance was accompanied with some acts of violence; but we are gratified to be able to state that there is no evidence that any of the strikers were either participants or abettors in any such acts. The rioters were of that miserable, useless class of beings who are commonly known as "hoodlums," and who are seldom known to be guilty of seeking for or doing an honest day's work.

#### There Are Three Parties

To this movement as it now stands—the organized and combined societies or labor unions, the unorganized workmen, and the capitalists and employers. The first, though very small in number, as compared with the unorganized workers, are nevertheless strong by virtue of combination. The second comprises "the silent many," who are ever ready to enjoy any substantial gain which may be fairly won by the few who are organized. These comprise the great bulk of the conservative masses, who will never become a party to any undue aggressive measures which may be instituted by their more aggressive friends in the labor organizations. The labor unions cannot succeed in any measures which do not meet with the indorsement of "the silent many." Should any such attempt be made and persisted in, the unions will fall to pieces like a rope of sand, and the leaders in any such attempt will, as a general thing, be ostracized from labor privileges.

#### There is a Universal Law

Which pervades every department of industry, and which governs, with an iron hand, all things connected with human operations, whether industrial or professional. This law is as unchangeable as the law of gravitation. The law of supply and demand governs every trade, every profession, every industry of every nation. No human organization or power can change it. When there is an over-supply of any commodity, that commodity will fall in value. When the world's crop of wheat is short, wheat is dear, and vice versa. When there is a scarcity of help in any particular industry, that class of help will be high. When more men than are needed are seeking for work in any particular line of business, wages in that line will be low. Organizations may modify the law to a certain extent, but they cannot annul it or even suppress it beyond a certain limited degree.

#### There is a Lesson in all This

Well worth learning—a lesson which may be valuable to many at the present time. There are "Unions" among laborers in which the individual gives up his freedom to a majority of his associates—some even to secret committees. There may be cases, in fact there have been, where these unions have been ruled by men who are lacking in judgment, who are too inconsiderate in their demands, who have gone beyond the wishes and wills of their associates. Several instances have occurred during the present labor troubles in which such officers have been compelled to take the back track and modify their demands. There have been symptoms of this kind among some of the strikers in this city. Men without families, or men who care nothing for their families, are inclined to risk more in their demands than those who have families and who recognize the duties they owe them. A lamentable example of this kind has been manifested in the great elevated railroad strike in New York, where wages and hours—the essentials of labor—were made to give way to a trifling matter of punctiliousness as to certain men whose discharge was required of the company. The consequence has been the cost of not less than a million of dollars to the workmen of that city, and the loss, to all the striking employees, of their positions, to which has been added a "boycott" on the part of the railroad managers which effectually keeps them off from any other road. To all this may be added a terrible amount of suffering and destitution among the strikers; and the end is not yet.

What reasonable man is there who will not say that the point hoped to be gained was not worth the merest moiety of the loss incurred? A small number, who had nothing to lose, took from a thousand men their means of livelihood and hope for the support of their families for an indefinite time. The men in whose hands such power is placed should carefully consider the consequences of their acts. The men who delegate such power should see that they do not

place themselves in the hands of those who lack experience or wisdom in the ordinary affairs of life—they should recollect that their first duty is to be free men and not slaves, to the end that they may properly provide for themselves and families.

#### The Unorganized Workers

Comprise the great majority of the working people of the country, probably 90 per cent of the whole number. As we have already said, so long as the 10 per cent which constitutes the organized forces of the workmen keep their demands within due bounds, secure fair wages and reasonable hours of labor, their efforts will be approved of and heartily indorsed by the unorganized ones and the public at large. But when they overstep that mark there is danger. The fact should always be borne in mind that when any difficulty arises which leads to a strike, the number of unorganized workers thrown out of employment is often many times as large as the organized strikers. In such cases care should be taken that good cause exists for the strike. A few repetitions of unnecessary strikes will be sure to bring a fire from the rear. The labor unions of the country would have very little influence without the moral support and indorsement of the masses. The great masses of the people hold as a most sacred right the freedom of the worker to work when and where he will. Hence, the rule set up that "none but union men shall be employed" should be made as elastic as possible. A rigid adherence to that rule has already cost the workmen much trouble, and may cost infinitely more. It is perfectly evident that such a rule cannot be made applicable in all cases and in all localities. We intend, by these hints, to convey the idea that judgment and moderation should be used in enforcing such a rule. The few who have surrendered their right to exercise their own judgment in such matters have done much good in the interest of labor, but they should not allow success in what was reasonable to so becloud their judgment as to lead them into unreasonable demands. So surely as they do they will find an unorganized crowd at their heels, and a thoroughly organized army of employees in their front. Between the two they will be utterly crushed. This brings us to the consideration of the third party, which must be considered in the settlement of this great question between labor and capital. This third party, which comprises

#### Capitalists and Their Associated Employees,

Have not been idle during the events of the last few months. It is one of the most natural things to expect that they also should organize on the same basis and for the same purpose that the employees have organized. The New England cotton manufacturers were the first to take active steps in this direction. Their organization is now so complete that any effectual strike for anything which the great masses of workmen would not approve of would hardly be possible. Indeed, the knowledge of this fact has already stopped one important contemplated strike before it had reached any considerable headway.

The manufacturers of brass and iron steam and water fittings were the next to organize. A strike for anything unreasonable among those workers would now be met with a general lock-out all through the Eastern States.

The shoemakers at the East have also effected quite a general and thorough organization, such a one as now pretty well commands the situation. This work of counter-organization is now being perfected all through the States east of the Rocky mountains, and the same work is also being inaugurated in this city. One of the good results which will inevitably follow from these counter-organizations will be that when both labor and capital are represented by strong organizations they will regard each other with far more respect than now, and the interests of both will be more likely to be protected by calm, judicious action. Under such dual organization arbitration will be more likely to be effective, and both sides will have less reason to dread hasty or unwise action or acrimonious conflict. The writer is not opposed to the organization of labor or trades unions. He holds that such organizations are an essential element in enabling labor to secure its just rights. Our only fear is that the management of such organizations may, to a certain extent, fall into the hands of those who may lack judgment and intelligence to use them discreetly and for the true interests of the laborers. Such organizations, conducted with intelligence and good judgment, are indispensable to the present condition of the industrial interests of the world. The public has already regarded with admiration most of the movements of the labor organizations throughout the country. The admirable lessons inculcated by Mr. Arthur, the president of the organization known as that of the Locomotive Engineers, and by Mr. Powderly, the head of the Knights of Labor, have done much to dignify labor and command respect for its representatives from all classes of society. They are really the two representative men of the labor interests of the country, and their utterances by word of mouth and through the press in regard to strikes, boycotts and the means in general which should be adopted to bring about a permanent settlement of all differences between labor and capital are worthy of all respect, and meet with most hearty approval from all intelligent, well-meaning laborers, and from most capitalists and employers as well. Their utterances are most

fully indorsed by the masses of the people, and all labor organizations which make them the basis for their demands and efforts will be most triumphantly sustained.

#### Words of Gold.

Mr. Arthur speaks wisely and truthfully when he says:

There should be no antagonism between capital and labor. There is no occasion for it. And, though I want every laboring man to hold up his head and look his employer squarely in the face, I want him to remember that capital, as well as labor, has rights which we must respect. We should strive to bring them closer together. We have no business to say that any employer shall employ or shall not employ this man. We have no right to go to the company and say: You must not employ that man. We oppose this way of doing things on principle.

Mr. Powderly, in speaking of his associates in the Trades Unions and Knights of Labor, says:

We are no more the salt of the earth than the millions of unknown toilers who do the work of the world. In our dealings with laborers and capitalists, we must deal justly and fairly by them. If we would have justice done to us, we in turn must do equally to others. This is the aim of the Knights of Labor and must not be lost sight of in the future.

Regarding boycotting, Mr. Powderly says: I find that wherever a strike occurs, appeals for aid are scattered broadcast among the assemblies. Do not pay one cent for such purposes in future unless the appeal comes from your own District Assembly or the General Assembly. If boycott notices are sent to you, burn them.

Men who own capital are not our enemies. If that theory held good, the workman of to-day would be the enemy of his fellow-toiler on the morrow; for, after all, it is how to acquire capital and how to use it properly that we are endeavoring to learn. No—the man of capital is not necessarily the enemy of labor; on the contrary, they must be brought closer together.

Mr. Powderly's plan is stated as follows:

I believe in combining all the scattered battalions of labor's mighty host in one grand whole. Labor-saving inventions, steam and electricity have forever broken the power of one trade or division of labor to stand and legislate for itself alone; and with the craft that selfishly legislates for itself alone, I have no sympathy.

#### Natural Gas in California.

The San Luis Obispo Republic says: The public has been aware that for some months past Dr. Nichols, Judge Adams and Mr. Walker have been engaged in boring for oil on the Doctor's tract of land near Miles Station, on the Pacific Coast Railway, and early in the week we paid the works a visit of inspection. A flow of oil has not yet been found, but there is a fountain of warm white-sulphur water from which rises a column of gas burning in a flame a yard in height. The locality is the base of the hill lying between San Luis creek and Cave Landing, fronting northeasterly, the hillside being covered with live oak trees and brush, while in the valley large sycamores, oaks, and willows are growing. The surface rock is generally serpentine, with occasional croppings of dark sandstone. In one of these sandstone croppings an exudation of oil had been observed, and it was determined to investigate and determine what the formation might bring forth. An excavation was made, and the rock blasted away was found permeated with petroleum, and when placed in the fire burned fiercely. With this slight prospect it was decided to bore in the usual manner for an oil well. Accordingly, a derrick was erected and machinery for working the artesian borers was devised and constructed by Mr. Walker; an engine of 16-horse power was then procured and operations commenced. At the time of our visit, a depth of 470 feet had been reached. Mr. Walker, who manages the work, has kept a record of the different formations penetrated, which, upon comparison, correspond very closely with the formations found in boring for oil wells in Pennsylvania. There, it is understood, three strata of sandrock must be passed before the flowing oil is reached. Here, two such layers have been penetrated, and now the auger is in the third. Before reaching the last stratum a flow of warm sulphur water was struck, and from the lower sandrock comes a large volume of gas. These now come up together, the water flowing at the rate of about 400 barrels a day, being heavily impregnated with white sulphur, and having a temperature of 85 degrees. The gas bubbles out of the water, and being lighted, sends up a flame about three feet in height, burning continuously. The boring will be continued until the sandrock is passed through in the expectation of striking oil. Should oil not be obtained, the well as it now stands must be considered of great value.

GLASS IN MELTING BRASS.—It is said that if brass founders will stir powdered glass into melted brass when in the crucibles, sound, nice castings will be the result. The claim is that the glass flux will collect all impurities, which rise to the top, and can be skimmed off, while otherwise the same impurities would be poured into the mold with the metal.

#### Copper Mine Litigation in Arizona.

The Tombstone Democrat of July 31st says: Judge J. S. Robinson, on Tuesday evening, informed a reporter of the Democrat that he had just received information from Tucson stating that the Supreme Court had sustained the decision of the lower court in the case of the Copper Queen Mining Company vs. Copper Prince Mining Company. The case, it will be remembered, was first tried in the District Court about three years ago, resulting in a complete victory for the Prince. In February last the case was again adjudicated in the County Court. In both trials the point at issue was virtually the same, although in the first trial the Prince was plaintiff, and in the latter trial that role was assumed by the Queen. The question was which company possessed within its boundaries the apex of the vein. As before stated, at the first trial this point was decided in favor of the Prince. The second trial was obtained on the ground of new evidence, the Queen Company claiming that developments made subsequent to the first trial would show that they (the Queen) had the true apex. The trial lasted more than two weeks. A cloud of witnesses on both sides were sworn and examined, including some of the most noted mining experts of the country. The jury found a verdict which was regarded as the result of a compromise, and was acceptable to neither party. By this verdict the Queen people were allowed about one-half of the ground in dispute. The decision of the Supreme Court, Judge Robinson informs the reporter, substantially affirms the result of the first trial, and is consequently regarded as a sweeping victory for the Prince. The judge also thinks this decision may be regarded as a final settlement of the case, and its results, he says, are destined to be of the utmost importance to Bisbee. The Prince Company will immediately proceed to work their property on an extensive scale. They will put on all the men that can be worked to advantage, and the extraction of ore and production of bullion will be pushed vigorously. Inasmuch as the Copper Queen will close down in a few days, the increased activity of the Prince will prove most fortunate for Bisbee. It is stated that the Prince will employ at least as many extra men as will be "let out" by the closing of the Queen. It is further stated that the low price of copper, which is the cause of the suspension of operations by the Queen, will not influence the Prince, their ore being of so high grade (running from 35 to 40 per cent) that it can be worked at a handsome profit, even at the present price of copper.

WHY SUNSTROKE IS RARE.—Sunstroke is extremely rare in California. The dry atmosphere prevents it. The rapid evaporation of perspiration from the skin keeps the whole body cool, just as water is cooled in a porous filter. Experiments that have been made show that the blood of a man working in the California harvest field, with the air at a temperature of 100 degrees or over, is little hotter than that of a man working in the cool air of the sea-coast. In the East, when the temperature is 90 or 95 degrees, men working exposed to the sun are frequently sunstruck. The moisture in the air there prevents the evaporation of perspiration, and the whole body becomes heated until something gives way. In California there are hundreds of men working in the sun where the temperature is above 100 degrees in the shade, and yet they are rarely disabled. Examinations were made a short time ago in the East as to the effect of trees on temperature. It was found that the shade of trees was cooler than that of any other object. In streets where the temperature was 90 degrees in the shade of houses, it was nearly 20 degrees lower under the trees. If people in California would plant more trees they would be cooler. Even if sunstroke is not to be feared, a temperature of 100 degrees is unbearable.—S. F. Report.

A STEEL-WIRE MAT.—The Hartman Steel Company, Limited, Beaver Falls, Pa., make a patent steel-wire door-mat which is meeting with much favor. It is made from steel wire, with steel frame and steel braces, all perfectly galvanized. They are wear and weather proof. Snow, ice, mud, clay and water are wiped out of sight by the slightest scrape. These mats are self-cleaning and require no shaking, and are adapted for any place where a mat or matting is needed. They are especially adapted for railway and street car floors, steamboats, hotels, offices, stores, residences, elevator floors, etc.

TO REMOVE OLD PAINT FROM GLASS.—Ten cents' worth of oxalic acid dissolved in a pint of hot water will remove paint spots from the windows. Pour a little into a cup and apply to the spots with a swab, but be sure not to allow the acid to touch the hands. Brasses may be quickly cleaned with it. Great care must be exercised in labeling the bottle and putting it out of the reach of children, as it is a deadly poison.

A SOUTH AMERICAN CONTINENTAL RAILROAD.—Mr. Clark, the great railroad man on the east side of the Andes, has given out that in two years the line from Buenos Ayres to Chili will be concluded, and thus direct communication by rail will exist uninterruptedly from the Atlantic to the Pacific ocean.

## Passing Events.

The mining regions of Idaho are showing considerable advancement of late, as the accounts given by our traveling correspondent, in other columns of the PRESS, prove. Some of the districts there are making a remarkable showing.

The shutting down of one of the prominent mines at Tombstone, Arizona, is bad for that camp, though the citizens there still continue hopeful.

The shutting down of several large Montana mines, owing to low prices of silver, will doubtless be followed by other mines elsewhere if the price of silver continues as low as at present for a much longer time. The discount on silver is very detrimental in many camps, and already in some places miners' wages have been reduced in consequence. Where the ores are of low grade, the discount takes off all the profit of silver mining, so the mines will either have to lose money or stop work until better prices are realized for their products.

At the Meadow Lake mine 17 men are engaged in erecting the mill, and four or five men are employed in the woods. There is about 15,000 tons of rock on the dump, which, it is claimed, will net \$16 to the ton.

## Silver and the Mines.

Silver has evidently reached bedrock in price and commenced slowly to rise again; but the low prices have had a very bad effect on mining operations. At Tombstone, Arizona, the Tombstone Mill and Mining Company has had to shut down, leaving about 200 miners out of work. At Candelaria, Nev., miners have been discharged owing to low silver prices. The Sheridan mine, Tellurium, Colorado, has reduced wages from \$4 to \$3.50 per day for the same cause. The mine is idle, as the men would not accept the reduction. At Leadville, Colorado, mine-owners are discussing the situation and debating the best policy to pursue. No solution of the problem has so far, however, been discovered, and the only effect of the recent decline has been to stimulate work and offset the decreased value of the metal by larger productions. If it were certain that silver will soon advance, a large number of mines would unquestionably suspend their output temporarily, but as there is no assurance of an advance at an early day, few are seriously thinking of closing down.

Butte, Montana, has been in a state of alarm for some time on the subject and it has been feared that many mines would have to close down. It was thought that some 12,000 men would be thrown out of work this month. Latest advices from there, however, as will be seen by a paragraph in our mining summary, are to the effect that as silver has commenced to advance, the mines will not close down as expected. The depreciation of value represented the profit of the mines in that camp.

One solution of the present difficulty is that which some mines have already adopted, namely: to increase the output in proportion to the decline in the price of silver, until this and other countries shall adopt a bi-metallic currency in which silver will receive proper recognition. All companies are not, however, in a position to do this. Still, the gradual rise, now apparent, brings rejoicing to the miners. It is not a sudden jump but a gradual reviving, and all are hopeful that the price will go back to the standard of last year.

## Liquid Fuel.

The use of petroleum fuel is gradually but surely being extended. For a year or more past the Southern Pacific Company have been using it on some of the ferryboats with success. The *Thoroughfare* and *Piedmont*, among the large ones, have demonstrated the success of the fuel. The *Julia*, running between South Vallejo and Vallejo Junction, has been burning oil for some time. A move of the hand regulates the flow of petroleum, which is kept at a burning temperature by a pipe of hot steam running within the oil-conducting pipe. The oil reaching the furnace is thrown into spray and burns with great fierceness. The oil is a refuse from the refinery, thick and black, not ignitable until heated to a high temperature. It is brought from Alameda to South Vallejo, and the steamer receives enough in five minutes to last all day. From 500 to 600 gallons are used each day.

The large ferry-steamer *Oakland*, which is running between this city and the Oakland mole, on the Southern Pacific Company route, is to be laid up soon for about six weeks to have new machinery put in so as to burn petroleum instead of coal. This kind of fuel saves the wages of several firemen, as one or two men are, with it, all that are necessary in the fire-room. The oil is more easily handled than the coal, as it requires less time and a smaller gang of men to put it into the vessel. Passengers like to travel upon boats burning the oil, also, for it is cleaner than coal, as no cinders or soot are emitted from the smokestack.

The owners of the Oakland Cotton Mills are investigating the subject with a view of burning oil there instead of coal.

The use of this fuel necessitates, however, a change in the furnaces, where coal has previously been used, the same arrangement not answering well.

California is now producing oil very largely and the supply is increasing. The oil is being used in places in the southern part of the State under boilers, and every month adds to the number who utilize this convenient fuel. Coal is so high here that the liquid fuel saves a great deal of money, to say nothing of the convenience in handling.

## Wood River Gold Mines.

The Camas and Donavan Bonanzas—A Rich Gold Field Neglected.

[Written for the PRESS by FRANK W. SMITH, our Traveling Representative.]

Every Wood River newspaper, as well as every correspondence from this much-talked of great mineral field, gives glowing, and in many instances truthful, accounts of the vast silver and lead deposits of the Wood River country. Seldom do we see anything of her gold mines; so seldom, in fact, that the public are led to believe that gold-bearing formations do not exist within the borders of this celebrated district. This district, like all others, runs to extremes in working for the first mineral that was discovered. Had a gold mine been discovered here first, there is no doubt but that many of the producing silver bonanzas of Wood River would to-day be run over by prospectors in search of gold and silver mines, and would receive the go-by until gold mines would begin to require capital and work to produce dividends. Be this as it may, yet it is an indisputable fact that to-day in this (Alturas) county there are hundreds of thousands invested in silver and lead mines and costly plants and reduction works to run them, while lying almost alongside of them are great deposits of gold-bearing, free-milling quartz of a high grade, miserably equipped and half worked, or, what is worse, mismanaged or kept idle by "working assessments" only. If California, with all her fabulous deposits of yellow metal, could boast of a showing on and below the surface, in quantity and quality, considering the development done, that the writer witnessed to-day, her "oldest timer" would be astonished.

The properties visited are owned by two sets of individuals, and the first described, the Camas No. 2, I don't believe could be bought for \$500,000, if any one was fool enough to give that much for it. The Donavan group ought to be bought by some Western mining men and developed in a manner in keeping with its merits, but as to securing it the writer can give no information. It is enough to make a mining man want a writ of mandamus to force men to sell a property, with the showing these mines make, who would permit the "dibble dabble" development that is in progress in this group.

## Mineral Hill Gold District.

Eight miles a little southwest of Hailey, the metropolis of Wood River, the eastern line of the gold belt joins the western edge of the silver-bearing formations. The formations of the gold belt are granite on the east and granite and porphyry further west on the belt. This belt is about five miles in width, and traceable from 20 miles east, west to Atlanta, 60 miles and miles beyond. With the exception of the mines hereinafter described, little, if any, development has been made. The majority of the prospect owners are not only "poor as Job's turkey" but ignorant of the difference between a prospect and a mine. I judge their ignorance from some prices given on "indications" and "croppings." Every mother's son of them that has locations on the extensions of the mines mentioned below is waiting in hopes that these properties will develop extensively, and thereby enhance their "ground." As will be seen by the account below, mines in this district pay under the most adverse circumstances.

## Parallel Veins.

Two large ledges—they are "too big" to be called veins—extend from east to west, about one mile apart, across the entire length of the belt, the only difference being that the north or Donavan ledge appears to be a fissure lying in a granite formation, while the south or Camas ledge is a contact lying between granite and porphyry. The character, dip and grade of the ores of the two are almost identical, save that the Camas carries a trace of copper; the Donavan being entirely free of any base metals. Both groups of mines are directly opposite and about one mile apart.

## The Camas No. 2.

This claim is a full one, being 1500x600 feet. Course of ledge northwest and southeast; dip about 50°. The ore body is a mixture of white, reddish and decomposed porous or honeycombed quartz, with here and there great chimneys of quartzitic porphyry or granite. The firm quartz is the lowest in grade and least in quantity. The management gave me the average to be \$25 per ton, but the shipments of bullion during the past few months figured with the capacity of the 20-stamp mill would indicate that \$40 would come nearer—the fact that they are saving only 30 per cent to the contrary notwithstanding. The ledge has been developed by an adit tunnel 400 feet all in on ore, commencing five feet in width, and widening to 20, and in some places to over 60. At the breast of the 400-foot tunnel, which has gone in on the hanging wall, a 60-foot crosscut has been driven south to reach the footwall, and as yet is still in ore and no indications of the wall sought for. The ore body cut by this crosscut is more or less mixed with mineralized quartzitic granite, but of a grade that will pay handsomely if worked

in large quantities. Mining the ores here is accomplished at a trifling cost. The richest ore lies next to the hanging wall, that toward the footwall being more firm and flinty in character; 160 feet in depth from the surface has been made by the 400-foot tunnel. At the mouth of the tunnel a 70-foot incline has been sunk, the last 30 feet being in ore, no drifts having been made at the bottom to ascertain the width of the vein. Some 500 feet in stopes and levels have been made over the 400-foot tunnel, in a number of places reaching the surface, where there are a number of open cuts, out of which tons of high-grade ore have been taken. The mine is dry as a match and easily worked. It has some 1500 feet of development work and the vast ore body now exposed demonstrates the stability of the property. Ore is run 800 feet in two-ton cars on a track to the mill for treatment.

## The Camas Mill.

Situated at the head of a sloping flat at the mountain's edge, and almost a stone's throw above an abundance of fine water, high, and if not dry nearly so, stands the 20-stamp wet-process mill of the Camas No. 2. Spring water barely sufficient to supply the boiler is obtained by pumping. The theory that

"The mill will never grind  
With the water that has passed,"

is knocked higher than Gilderey's kite here, as the waters secured here are pumped back into elevated tanks and used until they look like molasses coming from a milk-pan on a cold day. The mill was built partly by the Colorado Iron Works and Fraser & Chalmers, the Daisy engine and boiler being put in by the former. The plant is an excellent one, and if given any decent amount of clean water would save at least 70 instead of 30 per cent of the gold run through. No plates nor screens can do good work with slum where water is needed.

## The Donavan Group.

One mile east, directly opposite to and parallel with the Camas No. 2 and its extensions, lie the Donavan group and extensions. This vein is similar in character and quality to the Camas, and will probably rival it in quantity when equally developed. The course is almost due east and west, with a dip that is less than 30 degrees until a depth of 70 feet is reached, when the ledge appears to straighten up almost perpendicular. If there is any virtue in regularity of course, size and grade, this group is more favored than the Camas. The following diagram will give the reader an idea of the relative positions of the mines of the group:

The following explains the diagram: 1, the Donavan, 1500x600; 2, Rustler Fraction, 520x600; 3, Donavan, No. 3, 1500x600; 4, canyon, 250 feet deep, crossing the Donavan.

The formation is granite. So far as developed the ore body has shown a greater portion to be from four to six feet wide, with chimneys that make chamber-like ore deposits 20 feet or more in width and many feet in length. The canyon, 250 feet deep, cutting through the center of the Donavan, has acted as nature's workman in demonstrating the depth of and the regularity of the vein as it goes down. Development is progressing on the group, the principal work being done on the Rustler and the Donavan. In the canyon, on both sides, two tunnels—one 90 feet west and one 70 feet east—have been driven in on ore; the breast of these tunnels, when continued 150 feet further, will be under 250 feet of ore, between that and the surface. About 140 feet above the lower or 80-foot tunnel in west from the bed of the canyon is a 40-foot tunnel in on a decomposed quartz that is honeycombed in appearance and blended with a quartzite granite of a reddish color and a semi-decomposed nature that pans like a placer claim and mines like a piece of corn bread. The higher up the hill on a level with the Rustler, which covers the crown of the hill on the west side of the canyon, this soft quartz increases in quantity, and raises in grade exactly as the ore of the Rustler proved to do. The vein across the face of the Donavan where opened and gone in on averages four feet, and mills from \$20 to \$40 per ton. The vein is exposed more or less in five different places on the Donavan. On the Rustler more work has been done and a fine showing of high-grade ore in quantities that would cause any set of men, with less "irons in the fire" than the owners of this group, to "whoop up" development and treatment of the big output the group is capable of producing. An adit tunnel in ore 135 feet shows a large vein of porous quartz, that varies in width from 5 to 20 feet near the surface and runs from \$20 to hundreds per ton. I took a number of samples from different parts of the mine, and it horned like virgin placer ground, only it was finer gold. In some of the chimneys or chambers of ore a body of mineralized quartzitic granite often swells the ledge to an enormous size and reduces the grade of the ore according to the extent the less mineralized matter predominates. A depth of nearly 150 feet and some 400 feet in tunnels, inclines and stopes has been made on the Rustler near the west end line of the Donavan. All this work has been in ore and of a grade that will aver-

age from \$25 to \$60 all through. The Donavan No. 3 has but little development, but enough has been done to know they have the vein "all same" as the more developed of the group. This group is owned by a practical miner of limited means, who has a few non-resident associates interested with him, who have already more mining investments than they can do justice to, and, in consequence, they fail to assist the development in proportion to their interest and ability. Not because they have no faith in the property, but simply because they started in on silver mines and one or two of them are not ready to push gold properties. O. Rorem, a well-known mining man of Colorado, is superintendent and part owner, and he will more than likely get some California or Colorado capital to join him and open up this excellent property as it deserves to be handled. Wood and water are plenty. Every advantage for all season working is to be had here cheap. A 40-stamp mill on this group would produce more bullion every month than the whole Wood River district, with the exception of some of the large-producing bonanzas like the Minnie Moore and like properties, does in that time. If Superintendent Rorem had charge of this group for a company with money to put in a mill, instead of being interested with disinclined and elsewhere-engaged associates, Wood River's gold mines would soon be nearly as much talked of as her boasted silver and lead properties.

#### District "Pannings."

Good—the roads.  
Fine—the climate.  
Plenty—prospects.  
The Camas mill cleaned up \$5000 in July.  
Wanted—capital, and men who know how to invest it.  
Mineral Hill district gold is worth from \$15 to \$17 per ounce.  
Only six men are at work on the Donavan group at present.  
No work to speak of has been done on any of the extensions of the Camas No. 2.  
The Camas No. 2 is owned by James Doniphan and brother and a few St. Joseph, Mo., capitalists.  
The tailings of the Camas 20-stamp mill, now run with thrice used water, will assay higher than the ore.  
Over 6000 tons of tailings are saved up below the Camas mill that will pay better to work than the ore out of the mine.  
The district boasts of a Wiswell mill that was put in under a guarantee to work the ores

#### School of Mines Laboratory.

A few points in the construction and equipment of the new chemical laboratory of the Missouri School of Mines may prove of interest to those who contemplate erecting buildings for such work, especially where they are limited as to funds.

In this laboratory every room is well lighted; all rooms used by students are well ventilated and are provided with closed hoods for acid evaporations, etc. The ceilings in the qualita-

tory, and spacious hoods, which work well and do all that is claimed for them. Each of the main hoods is 12 feet long by 26 inches deep, and has three easily-sliding windows. The height of the hood is 10 feet, and that of the table three feet three inches. Some of the hoods are provided with basins and water; all are provided with gas. They are made tight above, so that all the air exhausted by the flues must enter the hoods under the windows. Each hood is ventilated by a flue 9x18 inches, which is a special compartment, built in the main stacks

NEW LABORATORY OF SCHOOL OF MINES OF MISSOURI.

tive and quantitative laboratories are high, being 16 feet at the walls and 19½ feet at the center of the rooms, where they take the form of a large panel. These high ceilings are very pleasant, and we find no difficulty in keeping the laboratories warm in the coldest weather.

The laboratory is a one-story building, as is

solely to ventilate the hood. At the bottom of the flue a gas-jet may be used, if necessary.

These hood-flues terminate at the top of the heavy 12 inch iron smoke-pipes, which are used in connection with the heating furnaces. These pipes terminate about 12 feet below the top of the stacks, which are 52 feet high. In the

the operation of the hoods has been thoroughly satisfactory.

Fig. 3 represents a section showing one of the hoods, main stack, ventilating-flues, etc.

In cold weather, thorough ventilation is secured by very large ventilators, two at the floor and two at the ceiling, in each laboratory, connecting with the air-chambers in the stacks. In the wall between the two laboratories, at the height of the ceiling, are two very large transoms, each 4x8 feet, which may be opened and shut at pleasure. These transoms, in connection with the windows in the two laboratories, furnish a system of ventilation, in the summer time, which is highly satisfactory.

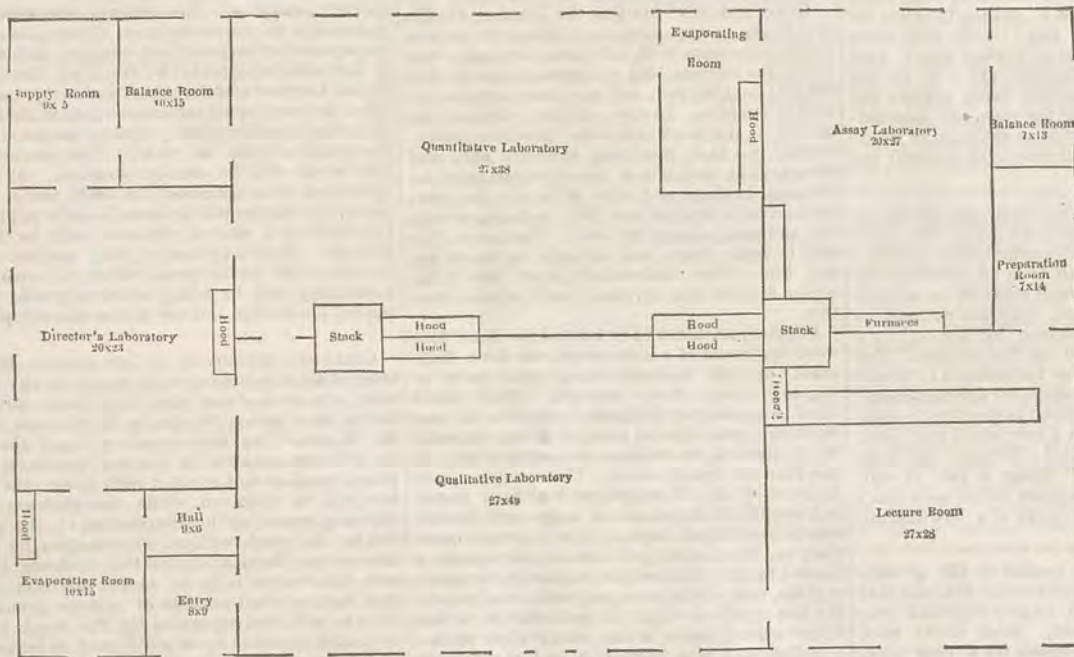

For valuable suggestions which aided Prof. Wait very much in the planning and subsequent equipping of this building, he is indebted to Dr. J. W. Mallett and Professor Dunnington, University of Virginia; Professor Ira Remsen, Johns Hopkins University; Dr. Chas. Doremus, New York; Dr. Eugene A. Smith, University of Alabama, and others.

#### Mining Accidents.

Frederick Hoffman, aged about 30 years and a native of Wurtemberg, Germany, went "on shift" at 7 o'clock Saturday night in the Derbec drift mine, Nevada county. He had not been using his pick more than three minutes when a miner working near him heard a groan, and looking around saw him lying on the ground. The young man had been struck in the back and on the right side by a large boulder which had become detached from the roof of the drift. His ribs on that side were mashed in, his liver crushed, and one of the broken ribs had apparently punctured a lung. He was taken to the surface and lived two hours.

Two miners—Fleming and O'Brien—were injured by a powder explosion last week in the Prince George mine, Stockton Hill, Arizona.

Nicholas Wilcox, of Garden valley, accidentally fell into a shaft at the Hart mine, near

PLAN OF CHEMICAL LABORATORY OF SCHOOL OF MINES.

SECTION OF HOOD, MAIN STACK, ETC.

satisfactorily. It has proved a failure, I am told.

Only \$500,000 is asked for the Camas No. 2. Any man who has that much money to buy a mine with—don't want any mine.

This district is reached from Ogden via the Utah Northern and Oregon Short Line to Hailey, thence by regular stages eight miles west to the gold belt.

The ores of the Big Camas, which is the second western extension of the Camas No. 2, run higher than the No. 2. This can also be said of the Donavan group.

Doniphan is the name of the new postoffice at the Camas mine. A town-site has been taken up, but owing to the scarcity of water the place has not been advertised much yet.

A fine mill site, with an abundant supply of water the year round, is owned by the Donavan group people. It is located below, and about the same distance from each other.

Only 10 stamps of the Camas No. 2 are run, owing to the scarcity of water. By moving the mill a few hundred yards lower down, water for a hundred stamps could be had.

The work being done on the Donavan group

(Continued on page 128.)

shown in elevation and plan, Figs. 1 and 2. It has a commodious basement under the quantitative laboratory, in which are located the large anthracite furnaces used in heating the building; provision is also made in this basement for locating large furnaces for metallurgical work, if necessary. Assaying is not done in the basement.

Suitable arrangements are made for that work in a properly-equipped assay-laboratory on the main floor. Ample provision is made for gas and water. The latter is delivered to heavy porcelain basins with small perforations in the bottom, no metal being placed below the lead ring and flashing which make a finish for the top of the table.

The prejudice against hoods for acid and other objectionable work induced Prof. Wait to look with no little interest into the matter. Some chemists, as is well known, prefer evaporating-rooms. He has, in this instance, provided both evaporating-rooms, one for each lab-

lecture-room and in the quantitative laboratory the hoods have not only the flue just mentioned, which ventilates the hoods from above, but a downward draft commencing at the top of the table, and passing into the main air-chamber, 2½x3 feet, in the stack, through which passes the smoke-pipe. In this way they secure in these hoods not only an upward current, but at the same time a downward draft. This system (described in a "Note on the New Chemical Laboratory of the Missouri School of Mines," by Prof. Chas. E. Wait, before the American Institute of Mining Engineers) is found to be all that could be desired.

In cold weather sufficient draft in the hoods is secured by the fire in the heating furnaces and by the movement of air outside, the building being isolated; while in warm weather, if necessary, gas is burned in the flues, or fire in a wind-furnace built in the basement for this purpose. To the latter expedients, however, they have not yet had to resort. In a word,

Georgetown, El Dorado county, breaking one of his legs between the ankle and knee.

NO PLACE FOR POOR MEN.—A number of prospectors and miners have returned to Juneau from the lower coast of Alaska, having been unable to obtain employment. Not having the means to support themselves, they are seeking transportation to more profitable shores. The *Alaskan*, published at Juncaw, says: "No man should come to this country without the means to sustain himself for some time. There is work here to do, and a good deal of it, but there is no great demand for labor, outside of that which is already employed. The companies and individuals doing business are generally supplied with all the help they need, and in most cases have supernumeraries from whom to draw their extra labor when required. Prospecting is laborious and expensive, and a man should come with a sure situation, or the means to invest in something that will pay."

## MECHANICAL PROGRESS.

## Petroleum as a Boiler Scale Resolvent and Preventive.

The use of crude petroleum in steam boilers for the purpose of preventing scale formations has prevailed for many years, with more or less success. The fact that 85 per cent of the material used vaporizes at a lower temperature than that of the boiler (350° F.), leaving little less than the tar or residuum behind, has been the greatest drawback to its complete success.

The possibility of the tar going over with the steam and obstructing valves has been a further objection to its use.

A heavy natural oil, free from tar, reduced by distillation until a fire test of 600° F. is reached, and compounded with elements having valuable solvent properties, has received the highest commendation by the leading steam engineers of Pittsburgh.

The insignificant cost of from seven to ten cents per week for the largest-sized boilers is a great item in its favor.

A quart per week, placed in the boiler after washing out and before filling, is all that is required. The action of the oil is more of a mechanical than chemical nature.

As the water rises the oil coats the shell of the boiler, as also the flues or tubes, and the impurities in the water, whether they consist of sulphates, carbonates or mud, make a greasy emulsion that will not cake or crystallize on the iron.

In from three to eight weeks after using, all old scale will disintegrate and pass away, leaving the iron in perfect condition, and no new scale will form, no matter what the character of the water. After a few weeks' use the mud drums, legs and parts of the boiler not subjected to the greatest heat will be found literally smeared with oil, while such parts of the boilers as receive the greatest heat will be as clear and bright as new iron. As petroleum is proof against acids, this coating of oil is absolute proof against sulphurous water.

A large establishment in Pittsburgh has been using petroleum solvent in their boilers for three years without spending a cent for repairs, while previously the boiler-makers' gang were at work on them every Saturday night in the year.

Worse scale could scarcely be found before the use of the solvent, while now their condition is pronounced by the inspectors as the cleanest boilers in the county.—*Am. Manufacturer.*

**CURIOSITIES OF METAL-WORKING.**—Recently, at a meeting of scientific men in England, a speaker produced an anklet worn by East Indian women. This is a flat curb chain about one inch broad, with the links very close, and weighing about 10 or 12 ounces. It is composed of a species of brass composed of copper and lead, without any trace of silver, zinc or tin. Such anklets are sold for a few pence, and they are cast all at once, complete as an endless chain. The links show no sign of having been united in any way. How it was possible to produce such a casting as this passed his comprehension, and he hoped that some one who had seen them made would explain the nature of the process. From the East much that was curious in metallurgical art came. Cast iron was, he believed, first made purposely in China. It was, however, frequently produced unintentionally when wrought iron was made direct from the ore in little furnaces about as big as a chimney-pot. It was found among the cinders and ash of the charcoal fire in grain or globules, which were not only like shot but were actually used as shot by the natives. He showed what he believed was the only specimen in England of this cast iron, in a bottle. He next referred to the celebrated Damascus blades of Indian swords, and explained that these blades were an intermixture of wrought iron and hard steel, which must have required great skill, time and patience for its production. One pattern in particular, known as "Mary's Ladder," showed wonderful finish and accuracy. Concerning the tempering of these blades little was known, but it was stated that it was effected by a long-continued hammering, or rather tapping, of the blade while cold.

**CASTING GLASS.**—It is reported that M. F. Siemens has perfected the process for casting glass as if it were a metal, and that in a short time an experiment will be made with the material to ascertain how far it will serve for railway sleepers. In addition to its toughness and endurance, the glass cannot be affected by the atmosphere, like other materials. The process is said to resemble the one in use for producing cast iron; but, instead of sand, finely-pulverized porcelain is used for the molds. The material is obtained by depositing molten glass on plates of metal, and causing the mass to cool quickly. The quality will depend on the character of the metal employed for the plates. When iron plates are used the glass produced is about three times as strong as ordinary glass; but with copper, which cools quickly, the standard of strength rises to eight times. Cast glass will not be more expensive than cast iron.

**TEMPERING BRASS—HOW IT IS DONE.**—Some considerable discussion has been carried on as to whether brass can be tempered. One of the writers, in affirming that it is capable of this

treatment, has thus expressed himself: "Brass, not hard by mixture, but by compression, either by rolling, hammering, wire-drawing, or any other process which compresses the particles of metal, can be, and is, tempered regularly, just as easy and in the same manner as an equal-sized piece of hardened steel would be tempered, viz.: by heat. By placing a small piece of polished steel on the brass object to be tempered, and applying the heat so as to affect equally the brass and steel, the color of the steel will indicate the temper of the brass, and by this process the brass may be tempered in exact proportion to every shade of color of the steel."

**AIR BLAST IN PUDDLING.**—An improvement in the manufacture of puddled iron and steel, introduced by a Monmouthshire forge manager, consists in subjecting the molten metal while in the puddling furnace to the action of a blast of air. By the special construction of the furnace these processes are carried on simultaneously. In place of the tuyeres commonly used for conveying the blast to the molten metal, one or more holes in the front, back, or sides of the furnace perform this function. Directly the metal begins to sink to the bed the blast is shut off, and the iron or steel is made into balls and conveyed to hammers or squeezers, as the case requires. The inventor's claim is: Simultaneously refining and puddling molten metal by submitting the said metal to the action of a blast of air in a puddling furnace substantially as described.

**AMERICAN-MADE ANCHORS.**—It is said that chains and anchors of American manufacture have not the standing and reputation they deserve, especially abroad, only because there can be no guarantee given the purchaser as to quality of iron and workmanship, such as would be given by public supervision and compulsory testing. Foreign vessels in American ports buy foreign anchors and chains, and vessels supplied by American manufacturers are refused insurance abroad. In order to remedy this defect, Mr. Morrow, of this State, recently introduced a bill into the House providing for the designation of a board of naval officers to test American-made chains and anchors, and thus place them on a par with those of foreign make which are tested, and hence may be guaranteed.

**A MECHANICAL PUZZLE** has been propounded which bids fair to enlist as much speculation as did the late problem of the movement of the carriage wheel. A pair of car-wheels and axle are resting on a piece of level track. A rope made fast to the axle and so wound round it that when the rope is pulled the tendency of the wheel is to come toward you; while at the same time if the wheels must revolve they must move from you. If the rope is pulled, in what direction will the wheels run? Will they move away from the spectator or toward him? Further, if the track is inclined, say 1 in 10, the highest part of the incline being nearest the spectator and the end of the rope, and a considerable strain being exerted on the rope, in which direction will the wheels move, up or down the incline?

**WIRE NAILS IN COILS.**—Perhaps, according to the *Pittsburg Dispatch*, we are to have wire nails by the yard. Henceforth this youthful antagonist of the cut nail is to be marketed by the coil, attached to each other by an attenuated thread of steel, and they are not only to be sold but are to be driven by the coil by a patent machine devised for the purpose. But how will these nails be for straight? Won't they be in an excellent shape for driving around corners? And how are the carpenters to separate these nails, as even a very small steel wire is a tough thing to break? Perhaps they may bite them off, or "tote" along a pair of nail-plate shears. Somehow, these coiled nails don't appear to carry the ear-marks of a bewildering success.

**STEEL RIVETS.**—The results of the government tests upon steel rivets would indicate that this metal is destined to largely supplant iron in another important field. Steel rivets have been used for special purposes for a long time, but their use up to the present time, in boilers, has been limited. The great amount of ductility, and capacity for local distortion without fracture, taken in connection with its high resistance to shearing, seems to us to render this metal peculiarly adapted for rivets.—*The Locomotive.*

**HARD OR SOFT STEEL FOR BEAMS AND GIRDERS.**—The Germans have been making experiments with a view to ascertaining the relative strength of hard and soft steel and iron beams or girders. The results show that the soft steel girders were 22 per cent and the hard steel girders 66 per cent stronger than the iron girders, and the strength of steel girders was found substantially the same for the two flanges when similar in section.

**SAWING AND THRASHING MACHINERY FROM VERMONT.**—The Foundry Shops, St. Albans, have been working 14 hours a day, and recently shipped a large order for thrashing and circular sawing machines to California.

**TO FROST BRASS WORK** and give it an ornamental finish, boil the article in caustic potash, rinse in clean water and dip in nitric acid till all oxide is removed; then wash quickly, dry in boxwood sawdust, and lacquer while warm.

## SCIENTIFIC PROGRESS.

## Force, Power and Work.

There exists in the minds of many but a very vague conception of the meaning attached to these three little words. Not so much does the difficulty appear to be in getting at a general sense or meaning for the words, as to separate the general idea conveyed into its factors, and to discern clearly just what portion of this whole is meant by force, by power and by work. Let us therefore consider each in its order and study their composition and relation.

We all have a pretty good idea of what force is; but the difficulty appears to be to disconnect the idea of force with that of motion. We can easily appreciate the force of gravity when we see a weight falling to the earth; but it is more difficult to comprehend the force as still existing, after the body has reached the ground, tending ever to draw it nearer the earth's center whenever its supports shall be taken from under it. Force is exerted by the magnet as much in holding a nail against its pole as in moving it up there. When the nail was in motion, or the body was falling to the earth, there was power developed. Power is the product of force and space. If a magnet could lift a weight of one pound against the force of gravity through one foot, it would develop one foot-pound of power. If the force of a cylinder full of steam can push a piston against 110 pounds through three feet, it will develop 330 foot-pounds of power.

Now what is the difference between power and work? Work takes account of the time in which power is exerted. If the engine mentioned was 18 inches in stroke, it would have to make one revolution to move the load through three feet as above. Now, suppose the engine to run 100 revolutions per minute, we should have 110 pounds move through 300 feet in a minute, which would equal one horse-power of work. If the engine runs at 50 revolutions per minute, we should have only 150 feet per minute. Work is the consumption of power, and the horse-power—the measure of work—is the measure of the rate of its consumption of power. It is evident, therefore, that a machine, the resistance of which it requires a certain force to overcome, will require twice the horse-power to overcome its resistance twice the number of times in a given time, and that it is not the pounds of force which a machine is capable of exerting which qualify its consumption of power, unless we take into account the distance through which this force is exerted.

## A Scientific Work of Art.

Under the above heading the Dresden *Anzeiger* refers to an apparatus for dividing circles into minute divisions with automatic accuracy—the work of a German long employed in the United States Coast Survey, and now once more a resident of Dresden. To mark off the division in the circles of the most elaborate "precision instruments" is a task requiring immense skill and accuracy, as each one of the divisions must be identical in shape and size with all the rest; each circle is divided into 360°, each degree into 60', and each minute into 60". This gives 129,600' in each circle, and delicate astronomical and some other instruments must have their circles divided into divisions much smaller than this.

Copying machines have heretofore done this work by means of a microscope, the lines indicated by the machine being gone over to engrave them deep enough. This hand labor is excessively fatiguing and arduous, and requires a great deal of time, it being impossible to divide a two-minute arc in this way in less than 36 hours' work. The machine constructed by Mr. Wurdemann has been tested and applied in all manner of ways until its success is established beyond the slightest question, and the accuracy of its work has become a marvel to all. It is set in motion by a small turbine, and works on calmly and evenly until the last stroke is cut. It performs in a few hours what it takes a man many days to accomplish, and with practically perfect accuracy. The machine is valued at \$12,000, and if no purchaser is found for it in Germany it will be brought to this country, and the United States may add another scientific laurel to their crown, and Germany and other nations will be obliged to send their precision instruments to this country to be divided.

**STRANGE IF TRUE.**—The African traveler, Dr. Giovanni Succi, who is at present in his native town, Forli, claims to have discovered a liquor which renders the human body independent of food and drink. In order to prove his assertion he placed himself under a medical committee who were to see that he took no nourishment for ten days, after having drank a few glasses of his liquor. At the end of that time the physicians pronounced his pulse perfectly normal, and in order to show that his strength had not suffered, Succi, before breaking his fast, walked from Forli to Forlinopoli, a distance of four miles, in 47 minutes. He then placed himself at the disposal of the medical faculty of Bologna, whose opinion in the matter is not yet known.

**FORMATION OF FOG.**—It has recently been demonstrated that in a perfectly moist air no formation of fog is possible, however much the temperature is lowered, so long as the air is

absolutely free from dust, and that the more air, sufficiently moist, is charged with such foreign particles, the more intense is the formation of fog. If filtered and completely moist air in a glass ball have its pressure diminished, only a few particles of fog will reveal themselves to the most careful inspection. But if a few cubic millimeters of ordinary house air be now admitted into this filtered air, a very fine, silvery, transparent fog at once forms itself, of such slight density that even in the case of a considerable area of it the transparency of the atmosphere would be but very slightly affected. At the first moment of its formation, if a reflected image of the sun, or the reflected light of an electric lamp, be viewed through it, the image will be seen surrounded by an intensely luminous blue or greenish light.

**ECHOES AT SEA.**—A new method of determining the near presence of icebergs on high shore lands, and even ships in a fog, has been devised by Mr. Frank Della Torre, of Baltimore. The device is based upon echoes, and has been thoroughly tested at Fort Carroll, by order of the Navy Department. This apparatus consists of a single-barrel breech-loading rifle, provided with a large funnel or speaking-trumpet on the muzzle, a box of cartridges and a tripod. The first experiment was made from a tug at a distance of half a mile from the fort. With the discharge of the rifle a distant echo was heard by those on board the tug, without the use of any receiving apparatus other than the unassisted ear. When a boat intervened between the tug and the fort, two echoes were heard, the fainter one coming from the vessel. In favorable weather the echo has been heard four miles. The steam whistle of the tug was also tried, but gave less distinct echoes than the sharp report of a rifle. A passing steamer about a mile from the tug gave a very distinct echo. Mr. Della Torre's signal was intended primarily to prevent collisions with icebergs in heavy weather, when it was impossible to be aware of their presence except by means of an echo, but is equally applicable in advising a ship's officer of the neighborhood of another vessel or other obstruction to navigation.

**MICROSCOPIC EXAMINATION OF IRON AND STEEL.**—The growing importance of microscopic examination of iron and steel is more and more recognized in Germany. In the May number of *Stahl und Eisen*, we notice that arrangements have been made at the government testing establishment at Berlin to render very valuable assistance to manufacturers, engineers, and others who may desire to make microscopic examinations of their materials. The cutting and preparation of the necessary sections is an operation requiring special skill and special apparatus. The testing establishment undertakes to prepare sections of samples sent, on payment of certain fixed charges, and, what is far more important, Dr. Wedding, the celebrated German metallurgical authority, undertakes to examine all sections so cut, if desired, and to see that they are properly prepared for the special objects in view. The charge for this work will be merely nominal. If the specimens to be examined are sent ready prepared, the charge will be from 75 cents to \$1.25. If a drawing is wanted, the cost will be from \$5 to \$7. Such a system, if fully carried out, cannot fail to be of great value to scientific metallurgy, and to bring about a greatly extended knowledge and use of the microscope.

**CELLULAR STRUCTURE OF CAST STEEL.**—Some interesting experiments with regard to the cellular structure of cast steel have been carried out at the Creusot Works, by M. Osmond and M. Worth. The experimenters found that if the thinnest conceivable sheets of the metal are placed on glass and covered with nitric acid the iron will be dissolved, while the skeleton remaining, revealing the distribution of the carbon in the steel, will, on examination by the microscope, furnish undoubted evidence that such distribution is by no means uniform, and that the cast steel consists of minute granulations in soft iron, separated for the most part by partitions made up of a different substance, a carburet of iron. In other words, cast steel is cellular in structure, the iron constituting the kernel, and the carburet of iron the shell. The elementary or simple cells thus constituted come together in composite cells or separate agglomerations in the thin sheets which are thus rendered transparent by empty lines.

**SEVEN COLORS FOR STAINING MARBLE.**—It is necessary to heat the marble hot, but not so as to injure it, the proper heat being that at which the colors nearly boil. Blue—alkaline indigo dye, or turnsole with alkali. Red—dragon's blood in spirits of wine. Yellow—gamboge in spirits of wine. Gold color—sal ammoniac, sulphate of zinc and verdigris, equal parts. Green—sap green, in spirits with potash. Brown—tincture of logwood. Crimson—alkanet root in turpentine. Marble may be veined according to taste. To stain marble well is a difficult operation.

**THE POWER OF RUNNING WATER.**—The power which flowing water possesses for transporting or moving stones and gravel over which it runs is very largely augmented by the speed of its flow. This power increases as the sixth power of the velocity; so that a stream flowing six times faster than another will be able to transport 46,656 times more matter.

## ENGINEERING NOTES.

**COAL AS PETROLEUM.**—Experience in the use of oil as a substitute for coal in making steam seems to be varied. With some it appears to be a perfect success; with others, a complete failure. Some scientific expert commission should be appointed to make exhaustive experiments under various conditions and with different oils, and make a full report upon the same for the benefit of the public. While newspaper reports generally agree that oil is a success, we occasionally notice adverse reports, as per the following, which we clip from a late issue of the *Shipping World*: "From Glasgow comes evidence of an unmistakable character that oil has been tried and found wanting. The managers of the Laird line, after a long trial of oil on board of one of their steamers, have decided, on purely economic grounds, to abandon it altogether as a fuel, having ascertained from practical tests, extending over a considerable period, that coal is the cheaper fuel of the two. Accordingly, they have had the oil tanks taken out of their vessel and have returned to the use of coal, notwithstanding the fact that the oil tanks and the apparatus for accomplishing complete combustion of the oil cost a considerable sum of money."

**THE NIAGARA BRIDGE.**—It seems that the Niagara bridge is fast becoming dangerous from the disintegration of the stone of which the suspension towers are constructed. So far has this deterioration progressed that it has been determined to replace the present stone towers with iron ones. It is intended that this work shall be done without disturbing the traffic, a work which will be not only a very difficult but also a somewhat dangerous piece of engineering. The work has already been commenced and every precaution to avoid an accident has been taken by Mr. Buck, the engineer in charge. Workmen are now making room on the sides of the towers for the preliminary iron work, and the stone is being chipped away with care by experienced men, who know just which ones to remove. On the tops of the towers men, who look like pigmies from below, are drilling in the caps so that when the time comes the hydraulic jacks may be applied and the great cables safely cradled from the stone supports which have held them up so long, and placed on strong iron towers which will replace the stone ones.

**ELECTRIC MOTORS FOR NEW YORK AND PHILADELPHIA RAILROADS.**—At a meeting of the New York Electrical Society, on the evening of June 23d, Mr. John M. Pendleton read an interesting paper on electrical railways, accompanied by a diagram of the proposed motor for street railways. Mr. Brackon, the attorney and agent in the United States for the celebrated electrician, Edmund Julien, was introduced and gave a brief explanation of Mr. Julien's system, as used on the Rue de Loure, at Brussels. A contract, according to Mr. Brackon, has already been made with Mr. Julien to have his cars, with their electrical accumulators, placed upon roads in both Philadelphia and New York, probably within the next five weeks. The particular road in New York has not as yet been decided upon, but will, no doubt, be the Broadway line.

**A GAS STREET RAILWAY MOTOR.**—A St. Louis man has invented a new motor for street cars. It is an engine receiving power from gas from coal oil. The oil is in a tank in the roof of the car, the gas being generated as used. The flash of the explosion as it passes into the cylinder heats the air, producing expansion. The only difficulty so far has appeared to be the nervousness of the general public in riding on or near a car carrying oil; but it is claimed that there would be absolutely no danger whatever. The inventor claims that he can furnish power for a 10-horse engine, which would pull three or four cars, at a cost of one dollar a day, the engine working noiselessly. The engine would occupy no more space than the lever in a grip car.

**PILE DRIVING BY DYNAMITE.**—An engineer of Pesth has lately used dynamite for driving piles. A circular cast-iron plate, 15 inches in diameter and 3½ inches thick, is fixed on the pile to be driven in a perfectly horizontal position. A dynamite cartridge made in the form of a disk, six inches in diameter and three-fourths of an inch thick, and containing 17½ ounces of dynamite, is placed upon the cast-iron plate and exploded by electricity. It is stated that the depth to which the pile is driven by each explosion is equal to five blows of an ordinary pile engine weighing 14½ Vienna cwt. falling 9 feet 10 inches. A cast-iron plate, on an average, resists 25 explosions.

**A CABLE TO BRAZIL.**—In view of the lack of interest manifested at Washington in building up our South American trade, a few enterprising Eastern merchants have determined to lay an ocean cable from New York to Brazil. What the railroad and telegraph are upon the land, the cable and the steamship are upon the sea—they must go together. The projected cable will be in operation in January next, and it is to be hoped that a steamship line will also be established at an early day.

## USEFUL INFORMATION.

**HOW TO ARRANGE A BOUQUET.**—There is much skill and taste to be used in arranging a bouquet, which any one may learn by attending to a few simple rules which may be given as follows: Arrangement of color is the principal item of success in a bouquet. The best known primary colors are red, blue and yellow, and among the compounds are orange, green and violet. To combine all these well we must turn to the artist, and he will tell us that good contrasts are orange and blue, yellow and green, yellow and purple, red and blue, red and violet, red and green, etc. White may be termed a dead color, and can come in almost anywhere, except between a very dark and bright color, where gray is better. Black does well to divide conspicuous colors like red and orange, for it does not produce such a violent contrast as white would do. If the bouquet is to be entirely shades of one color, red is valuable; commencing with deep scarlet in the center, and putting round it rings of brick-red, deep carmine, pink, pale red, rose, and a boundary of white or green. Care has to be taken to choose flowers that will keep their petals, and for this, flowers in bud or just opened are the best. It is bad to see a bouquet of flowers like full-blown geraniums or primulas, for in a very short time the bouquet will be a mass of vacancies. In putting the flowers together, it is better to start with a substantial central flower, like a rose or camellia, and bind the others round it, keeping the size, shape and arrangement well in view. If the stalks are short, lengthen them with wire, and never put on a fresh flower till the last is well secured, or often, just as the bouquet is finished, the center will fall out.

**STILLING TROUBLED WATERS.**—Experiments with the use of oil for controlling sea waves in a storm are continually being reported, and almost or quite universally with the most marked success. The wonder is, that any one, with the evidence now accumulated, should ever think of going to sea in any kind of a craft without every needed appliance for this mode of protection; and still very few sea captains avail themselves of it. The latest report of the kind is given as follows: Captain Sawyer, of the barkentine *Vidette*, of Millbridge, says that he has never found anything better than porpoise oil to calm the angry seas. He is accustomed to make bags about the size of buckets out of gunny cloth, stuff them full of oakum and saturate them with the oil. The captain says that from one to three gallons will run a vessel through most any gale till the sea gets regular. Speaking of a voyage from Bangor to Bowling, Scotland, Captain Sawyer says: "While hove to in a westerly gale, I tried the experiment of taking in the forward oil bag, and in less than 10 minutes the sea boarded us forward and lifted the deck-load and flooded the whole fore part of the ship, while previously, and after putting the bag forward, we shipped no water. These combers of the sea would come down toward us turning over like the surf on the beach, just with the same noise attending breakers, but just as soon as they reached the oil all was hushed up; we rose on the top of it all, while ahead and astern of us it would go coming by in perfect fury."—*Lewiston, Me., Journal*.

**SUBSTITUTES FOR TEA.**—The dangerous adulterations of teas in China and in this country have induced much experiment in search of a substitute for the tea leaf from some of our native leaves. Each of the following is said to possess the merit of being cheaper and more healthy than common tea, while the appearance is nearly the same. The young leaves of the pea plant, or the young leaves and flowers of the strawberry, or the first leaves of the currant bush, or the herd spring grass (*anthoxanthum odoratum*), or the leaves of speedwell, wild germander, syringia or mock orange, purple spiked willow herb, sweet brier, cherry tree, sloe, etc. The above should be dried on tin in the shade, and afterward rounced up with a little calcined magnesia to impart a bloom. Black currant leaves similarly treated make a good tea.

**PEACH VINEGAR.**—A correspondent of the *Home and Farm* says a good, healthy vinegar, made from peaches, can always be kept on hand for table use. Procure a large stone jar, which must be kept for that purpose alone. During the peach season fill it with good clingstone peaches; do not peel them, but wash thoroughly. Make up sweetened water (rain-water is best) of good molasses or brown sugar and pour over the peaches till they are well covered; tie a single thickness of cloth over the jar, and soon it will be vinegar. Draw off, and fill again with sweetened water, as before, which will be ready by the time the first is used up, and so on until the next peach season, when fresh peaches may be put up for another year.

**IN CHIPPING IRON.**—To chip smooth after the chip has been started, the chisel should always be held at the same angle at which the chip was started, and every blow of the hammer should be as near alike as possible; then, with common sense and practice, a person can chip nearly as smooth as he can file.

**EBONY CAN BE IMITATED** on wood by first painting with a 1-per-cent solution of sulphate

of copper. When perfectly dry the wood is painted over with a liquid consisting of equal weights of aniline, hydro-chloride and spirits of wine. The blue vitriol acts on the aniline and forms nigrosin, a black which cannot be affected by acids or alkalis. A luster can be added by coating with simple copal varnish.

**TO RESTORE INJURED MEAT.**—When the brine sours or taints the meat, pour it off, boil it, skim it well, then pour it back again on the meat, boiling hot; this will restore it even when much injured. If tainted meat is immersed in the solution of chloride of lime prescribed for rancid butter, it will restore it. Flyblown meat can be completely restored by immersing it a few hours in a vessel containing a small quantity of beer, but it will taint and impart a putrid smell to the liquor. Fresh meat, hams, fish, etc., can be preserved for an indefinite length of time without salt, by a light application of pyroligneous acid applied with a brush; it imparts a fine, smoky flavor to the meat, and is an effectual preservative against its loss.

**A TRANSPARENT ENAMEL.**—It is said that the Hartford Silver Plate Company have discovered a transparent enamel, which they are applying to their hollow ware, which seems to offer complete protection against the tarnishing that has been such a perplexing element in the silverware business.

**CREMATION.**—In recent experiments in Paris, it was shown that a human body, of average size, could be entirely burned in a common stove in 40 hours, without a disagreeable smell. This is taken as an argument in favor of cremation, as it shows that the process need not be expensive.

**TO REMOVE CLINKERS.**—To remove clinkers from the stove, sprinkle common table salt on the linings when the stove is cold. Use plenty of it. Build a moderate fire—wood and coal—and in a day or two the clinkers will be gone.

**TO KEEP INSECTS OUT OF BIRD-CAGES,** tie up a little sulphur in a bag and suspend it in the cage. Red ants, it is said, will never be found in a closet or drawer if a small bag of sulphur be kept in these places.

**SPOTS IN VARNISHED FURNITURE** are often removed by rubbing them with essence of peppermint or spirits of camphor, and afterward using furniture polish or cold linseed oil.

## GOOD HEALTH.

### Sleep Habits of Children.

Many habits and customs, the deleterious effects of which are recognized, would become things of the past if a practical and simple remedy could be devised. I have never met with any plainly written advisory articles on the training of children in proper sleep habits, except as to time. A recent experience has led me to "study up" on the subject, in the most practical way, by asking questions of mothers and nurses. My little patient, whose habits and conditions led to this investigation, is 10 years old. A serious and chronic affection of the kidneys has resulted from excessive use of sweets, and consequently lack of appetite for, and assimilation of, nutritious food. She persistently sleeps prone on the back with the arms flexed above her head. Watching results in seeing her turn on one side from eight to ten times every night, but, of course, a further result is diminished sleep, although it is not more restless than usual. Whether the habit can be permanently broken up is difficult to say. From her birth she exhibited a preference for that position, and had been indulged in it, with the inevitable results of catarrhal affections, dry throat, enervating, restless sleep, and aggravation of the kidney difficulty, as the spine was unduly heated by constant contact with the bed.

From the hour of birth a babe should be laid down to sleep with great care; never should it be permitted to lie on the back while sleeping. After it begins to play, the restless limbs are very beneficially exercised while lying so; but so soon as sleep comes the little one should be gently lifted and placed on the side, with the head raised only sufficiently to insure the spine from any curvature, seeing that there are no folds in the clothing to torture the tender flesh, especial care being taken to lay the ear smoothly back. Alternate the sides, or there will be an unnecessary unevenness of contour when the child is grown. Do not permit the knees to be so flexed as to crowd the viscera. Lying on the stomach occasionally is not injurious if the arms lie at the side and the face is free to the air. Frequently that proves to be a very restful position to a play-weary child.

It is not a difficult matter to teach a child to sleep with the mouth closed and without snoring or "gritting the teeth." A lady of 35, who had habitually gritted her teeth from their first possession, was cured of the habit in a fortnight by persistent waking at the first indication of the sound. The habit has not been resumed during the five years since passed.

If mothers could realize how many people suffer from bad sleep habits contracted in childhood, they would pay a little attention to their children at night-time, beyond the "hustling

off to bed, out of the way," and the "keeping covered," which is a sort of "dim religious duty" kept sight of out of fear of the doctor's bill rather than of any other consideration.—*Exchange*.

### Various Remedies for Seasickness.

A very good remedy for seasickness is chloral, but whether it acts by simply benumbing the nerves of the stomach, or by reducing the susceptibility of the whole nervous system, we do not know. At all events, a passenger may take 30 grains of chloral at Dover, fall into a drowsy, half-conscious state, and find himself at Calais free from sickness. Sometimes one or two drops of pure chloroform taken in a wine-glass of water will prove efficacious. Hypodermic injections of morphia are occasionally resorted to, but their use is not justifiable until other remedies have been tried and failed. The substance known as petroleum, mineral naphtha or rock oil, enjoys a high reputation in the treatment of seasickness. It should be taken on going on board, a drop or two on a small piece of sugar, and repeated every two or three hours. A pill containing three drops of creosote is another good remedy. Ipecacuanha wine, in drop doses, which proves so successful in the treatment of many kinds of vomiting, would probably succeed in seasickness, although we are not acquainted with the records of any cases in which it has been tried. Recent experiments seem to show that cocaine is a promising and harmless remedy against seasickness. An authority on the subject recommends that the drug be administered in doses of ¼ to ½ of a grain, dissolved in water (1 in 10) three times a day, with a small piece of ice. A surgeon on board one of the vessels of the White Star line recently informed us that in obstinate cases he had often obtained relief by the use of iced dry champagne. It is essential, he says, that the wine should be dry, for sweet champagne only makes matters worse. In the Levant the daily internal use of iron is a very common cure for seasickness. Sailors, when suffering from this complaint, obtain their iron in a very primitive manner, for they scrape off a portion of the rust adhering to the anchor and anchor-chain, and then swallow it in a little water.—*Family Physician*.

**INCREASE OF HYDROPHOBIA.**—It is a most curious fact, says the *Herald of Health*, that there has been nearly twice as much so-called hydrophobia in France since Pasteur came into the field with his remedy as before. The cause, no doubt, is the fear of the disease, arising from the constant discussion of it in the papers. The effect of this on weak minds is very great. Who will ever know how many people die of fear every day? The physician who can allay fear will often succeed better than any other. In the same connection the *Herald* remarks that many persons who have been bitten by dogs have a sort of terrorphobia and die of it. It is not hydrophobia at all, but the result of fear. One man who had this terrorphobia, and who by powerful efforts of will lived through it, describes his sensations as being horrible in the extreme. He kept possession of his reason, however, but declared it was all he could do to keep from going mad. It may be pretty surely believed that any case of so-called hydrophobia occurring three or four months after the biting is spurious. There are genuine cases of this disease, no doubt; how many, nobody knows.

**REMEDY FOR COLD FEET.**—The following remedy for cold feet is recommended for sedentary sufferers, as well as policemen, car-drivers and others who are exposed to the cold: All that is necessary is to stand erect and very gradually lift one's self up upon the tips of the toes, so as to pull all the tendons of the foot at full strain. This is not to hop or jump up and down, but simply to rise—the slower the better—upon tiptoe, and to remain standing on the point of the toes as long as possible, then gradually coming to the natural position. Repeat this several times, and, by the amount of the work the tips of the toes are made to do in sustaining the body's weight, a sufficient and lively circulation is set up. A heavy pair of woolen stockings drawn over thin cotton ones is also recommended for keeping the feet warm.

**TO CURE REDNESS OF THE NOSE.**—A correspondent sends to the editor of the *Boston Globe* the following recipe to cure redness of the nose: "Sulphuret of potash two drams, tincture of benzine one-half ounce, glycerine one ounce, rose-water one and one-fourth pints. Dissolve the potash with a third of the rose-water, then add the benzine and gradually stir in the remainder of the rose-water." How this is to be used the writer does not explain. As a general thing a red nose will be most easily cured by changing the potatoes at the bar from whatever it may previously have been to lemonade.

**ANILINE OIL AS AN ANÆSTHETIC.**—Physicians are now using aniline oil as a local anæsthetic when simple operations, such as the opening of a felon, are to be performed. The finger, in such a case, is dipped for a short time in the oil, and although the flesh may subsequently be cut to the bone, it is said there is absolutely no pain.

The *Medical World* tells of a patient whose prematurely gray hair is returning to its natural color under the internal administration of phosphorized cod-liver oil.

## MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

## CALIFORNIA.

## Alameda.

**COAL.**—Livermore Herald, August 14: Jenkins Richards is about to make an effort to organize a company to continue the work he has been prosecuting for some time past at the Livermore coal mine. He is now in 460 feet and within about 140 feet of the vein. He has been working across the fault, following the loose and broken masses of coal. He is now, however, at a financial standstill, and must have assistance in order to go on. As soon as the vein is reached he will have an immense wall of coal to draw upon above the level of his tunnel, which can be taken out at a very small expense. There will be no hoisting, everything being on a level. There is certainly a fortune in this mine, and somebody will realize it while we are standing still. The vein is five feet in width and the coal of excellent quality. At some points the vein will reach from 400 to 600 feet above the tunnel.

## Amador.

**LOYAL LEAD.**—Amador Ledger, Aug. 11: This promising mine near Drytown continues to turn out handsomely. The last two or three crushings have averaged between \$7 and \$8 per ton in free gold. For last month's run the owners received a dividend of \$200 apiece after paying all running expenses.

**MISCELLANEOUS.**—At the Kennedy the material for the 40-stamp mill is arriving on the ground very fast. Six or seven teams are engaged in hauling from Ione. Next week the mechanics will commence to put the mill together. Two or three of the principal owners of the Consolidated Amador are expected here daily, their mission being to take some action with regard to the future of the mine. It is thought by many that an entire change of program will be made if operations are resumed; that the water will be taken out of the old mine to a certain depth, and a connection made between the two shafts. The Lincoln mine paid off this week. The ten-stamp mill of the Iowa is running satisfactorily to all concerned. The look of the plates warrants the belief that the rock will pay handsomely. Operations have been started again at the McIntyre mine north of town. Two or three men are employed. Mr. McIntyre is confident that it will turn out a good mine.

## Calaveras.

**AGAIN IN OPERATION.**—Calaveras Chronicle: The machinery at the Utica mine in this town having been thoroughly repaired since the explosion, started up last Monday for the purpose of freeing the mine from water. Work will commence in a few days. Mr. Lane, the superintendent, being possessed of untiring energy, lost no time in placing the mine in working order again. We welcome the shrill blast of the Utica whistle as in times past.

## El Dorado.

**TUNNEL.**—Placerville Observer, August 14: John B. Paginini was in Placerville Saturday. He says the tunnel in his gravel mine at Newtown is now in for a distance of 500 feet, in addition to the open cut, and that the gravel shows considerable free gold. While but a small force of men are now employed there is room for many more, who will be put on as soon as the necessary pumping machinery is in place.

**MINING ACTIVITY.**—There is great mining activity at Poverty Point. The quartz mill at that place is kept almost constantly at work on custom rock extracted in its vicinity. On Sunday last a four-days' run was completed on rock taken from the Hulbert Bros.' mine. At present the rock is being crushed from the mine of Cohn & Smith, while Gus Salcovitch has 50 tons of ore waiting at the mill to be crushed.

## Fresno.

**MILL RUNNING.**—Fresno Expositor, Aug. 14: J. McNally came down from the Abby mine last night. He reports that their mill is running steadily, crushing about 20 tons of ore a day, and yielding handsomely.

**TO BE SOLD.**—The Hildreth mine, adjoining the celebrated Abby mine, and fully equal in extent and richness, is advertised to be sold at trustee's sale on Sept. 10th.

**THE ABBY MINE.**—W. H. Tew, of Hildreth, came down yesterday. He reports the Abby mine as doing well. Their 10-stamp mill is putting out about \$1000 a day. Mr. Tew was making arrangements to have about 12,000 pounds of freight moved from this place to Hildreth, for the firm of Brower & Grayson. Everything is booming in that quarter.

## Lake.

**GOLD HILL.**—Lower Lake Bulletin, Aug. 14: At Sulphur creek the old Manzanita mine is again in operation and its little quartz mill is pounding away at its auriferous ore. Considerable money has been invested by the new proprietors in machinery and works at the Cherry mine, but they do not yet seem to have started up—at least there was no smoke from the huge smoke-stack the other day. Alex. Hunger and Mr. Williams are driving a prospect down on their coal vein which promises well.

## Mono.

**BODIE.**—Cor. Virginia Enterprise, Aug. 15: The old reliable Standard Con. Mill and Mining Co. is at present doing considerable work under the judicious management of Supt. A. Pettibone. The Standard half of the Bulwer-Standard mill is kept steadily at work crushing Standard ore, and report says will start the other side (Bulwer) on the same ore in a few days. Mr. Pettibone started the old Standard mill going on their surplus tailings. Some three weeks ago Captain Kelly, of the Bodie, Lent, Mono, Bulwer and Dudley Mining Companies, started in to remove the Bodie mill and residences from the old mill-site—two miles down the canyon—to the Lent shaft, which work will be completed in a month hence. This change will greatly facilitate the workings of those mines. The Dudley mine is going to be prospected through the Lent shaft. The Bodie Tunnel mill will start up again on Tunnel ore,

The mill will be under the management of Captain Buckley, superintending both mine and mill, an experienced millman and mechanic. Bodie has a brighter outlook to-day than for a long time past. Many old Bodieites who left this camp some years ago, for better or worse, are on the repentant stool and coming back. Notably among the many may be seen Malachi Norton, an old resident of this camp, and formerly constable of your city, coming to us from the land of cactus and rattlesnakes, and Jerry Ryan, another old Comstocker, returned yesterday, coming from Montana, Idaho, Utah and California. Old miners from Nevada and California mountains do not take kindly to tenderfoot camps, especially where they camp at night with the thermometer registering 120 degrees.

## Nevada.

**MORNING STAR DRIFT MINE.**—Grass Valley Union, Aug. 11: On Monday, Captain Frank Richards went over to Iowa Hill to visit the Morning Star drift mine, in which he and other Grass Valleyans are interested. This mine has been heretofore mentioned in the Union, having obtained rich prospects by making a raise from the tunnel into the gravel channel and then drifting along the channel for a distance of over 400 feet. The last gravel taken out yielded \$3 to the carload, and one man could take out two loads of gravel per day. At the point where the upraise was the tunnel was in 1900 feet, and it was found necessary to continue this tunnel 500 feet to bring it under the channel where the rich pay was found, in order to secure practical and economical working. To this end a contract was let to John Hobson, of Iowa Hill, to run 500 feet of tunnel, and he has had a force of men upon it for some months. The rock is found exceedingly hard, as many as 50 drills being used in putting down a single hole. Of late, the ground has been a little more favorable; but yet only about six feet of drift run under the contract, and it is hoped to complete the full 500 feet by the first of the new year. The work is tedious and expensive, but the rich prospects obtained is full encouragement, as when the channel is opened up a large output of gold will certainly be realized.

**ROCKY BAR.**—Grass Valley Union, Aug. 10: Twenty men are at work on tribute in the Rocky Bar mine. The hoisting and pumping machinery from the Eureka mine, Gold Flat, is being removed to the Lone Tree mine, of this district, and will be in running order on the latter mine in 10 or 12 days, when underground operations will be resumed. The Lone Tree was looking well when operations were suspended on account of the water.

**GOLD PRODUCERS.**—Tidings, Aug. 8: The Idaho is still looking first rate in its bottom or working levels. Good results are expected from the 1700 level, which is soon to be opened. The Empire is doing as well if not better than ever, and the new mill is the admiration of all who see it. The two large air compressors arrived here yesterday from the Risdon Iron Works, and are being taken from the depot to be placed in position at the mine. The Badger has a very good-looking ledge in the bottom of the shaft. While no free gold is visible to the naked eye, the ore is of fine quality. The ledge is widening out and it is hoped that better ground will soon be reached, as it is now extra hard ground to work. Mr. Wm. Body will, in all probability, soon commence making preparations for erecting a mill at the North Star. The mine is doing well; in fact, all that has been claimed for it—and the company will soon have a mill of their own. Tretheway & Co. have taken a contract for sinking the shaft of the Loami 50 feet, and also to pump out the mine. The shaft is about 145 feet deep now and contains about 100 feet of water. A six-inch pump is now in position at the shaft and the mine will soon be clear of water, when sinking will commence. The Loami is located west of the Adams ranch, and the company are searching for the famous Alta gravel lead, with good indications of being near it. One thing to be regretted: There are too many valuable quartz mines lying idle around here. The owners of these mines have plenty of money and are living elsewhere in ease and luxury. They have patents upon their mines and are perfectly independent as to whether they are worked or not. The work in the Horse Shoe mine, on Wolf creek, is going steadily ahead, and the company are not bothered nearly so much with water as they expected to be. The shaft is now down 140 feet, the contractors who are to sink it having made 10 feet already. The ledge in the drift is about 2½ feet wide and prospects well, many pieces taken from the ledge showing free gold, and all of the ledge being good ore. The Horse Shoe, it is pretty certain, is the same ledge as the famous Allison Ranch. The Lone Tree Company has commenced erecting machinery on its prospect. It purchased machinery from C. W. Cross, at Nevada City, and it is now being hauled to the mine. The Central mine, on Greenhorn creek, started up Monday under favorable circumstances. We expect before many days to chronicle some good results from this mine, for it looks well.

**THE CHICAGO CON.**—Nevada Transcript, Aug. 15: At the Chicago quartz mine on Gold Flat, near the Pittsburg, the third level is now being sunk for. The ledge is of fair size and quality. It is proposed by the parties who hold the bond to have some more extracted on tribute.

**MACHINERY MOVED.**—J. C. Locklin has removed the hoisting and pumping machinery that he put up some time ago on the Macklin ledge, to the Chapman Ranch ledge about 1000 feet below. He will thoroughly prospect the latter.

**THE MOUNTAINEER MINE.**—Transcript, Aug. 13: The work of erecting stronger hoisting machinery in the tunnel of the Mountaineer mine than has heretofore been used will begin shortly. The change will cost between \$8000 and \$10,000, and while it is being made the mill will be shut down more or less. When the new works are in operation, however, the mine can be worked to much better advantage than at present, and the increased output will in due time compensate for the outlay required for the improvement.

**QUARTZ.**—North San Juan Times, Aug. 14: A new quartz ledge has been struck below Buckeye Hill by J. P. Sudger and John McCoy. This is of the white quartz formation and prospects well. Good paying ledges are being found in this vicinity almost every day, which leads us to the belief that North San Juan is on the verge of a mining boom. The boss quartz mill is expected to arrive here to-day,

and will be put in place at once. The framework is all up and all that will have to be done will be to put the mill in position. Water will be taken out of the Milton ditch in a pipe that is already laid, and the mill will be run by a Pelton wheel. In our last issue we stated that the ledge in the Delhi mine, as then developed was 2½ feet wide. Since then it has been widening continually as the tunnel is driven ahead, until now the width is 8 feet. The rock is very rich, as the next monthly statement will show. We learn that for the present the rock will be taken to the mill on a tramway.

## Shasta.

**BULLION.**—Shasta Co. Democrat, Aug. 11: Last week Tom Greene brought down another good-sized chunk of bullion, the first cleanup from his new mill. It is reported that a New York incorporated company is soon to take hold of certain mining property on Squaw Creek. The Winthrop company has resumed work on the mine of that name at Copper City. A force of men are at work cleaning out the old tunnel and running one to tap a new body of ore. Peter Scheerer informs us that so far the process erected on his mine has proved satisfactory, with one exception, and that is, the plant does not reduce as much ore by consideration as was claimed for it. From 2400 pounds of ore, second class black slate ore, yielded \$400, a result far in excess of what was anticipated. He says the capacity of the plant is to be increased immediately sufficient to work ten tons of ore per day. Mr. Scheerer is in high spirits and feels confident of achieving grand success.

## Sierra.

**MONTPELIER.**—Mt. Messenger, Aug. 14: The owners of the Montpelier mine (the old Wheeler quartz mine) are expected out from Boston at an early day to examine the property with a view of developing it. The Wheeler ledge was very rich in the upper level, and paid well with the one-horse mill in use at that early day. A lower tunnel was run nearly 20 years ago and a good-sized ledge cut, but so far as we remember no prospecting was done. This tunnel was put in only about 300 feet. With improved appliances we can now work rock at a profit that would not pay 20 years ago. We hope soon to see one of Forbes' mills crushing rock from this ledge. P. A. Haven is making arrangements to further develop his quartz ledge at Gold Lake. The ledge was worked in early days and paid well. Another nugget of gold worth in the neighborhood of \$800 was found a few days since by Steelman & Hays at their diggings in Gold Lake district. The Pennsylvania company are preparing to start a tunnel to open their drift gravel claims near Cornish ranch. A shaft has been sunk 200 feet on the channel.

**GOOD NEWS FROM GOLD LAKE.**—Sierra Tribune, Aug. 14: A prospector was in from Gold Lake Sunday. He says that the owners of the Forest King are pretty sure they have a big thing. They have a drift in on their ledge 70 feet. The vein is about three feet wide, of solid quartz that they believe will average \$50 a ton. The drift is being pushed ahead. This mine is owned by Loyaltan parties. A shaft has also been sunk on what is known as the old Rhodes mine. This is owned by parties from the Valley.

**MEADOW LAKE BOOM.**—We learn that matters at Meadow Lake are "booming." The company are building a fine road to Cisco, on the Central Pacific, which is said to be 12 miles from the mines. Lumber is going in from about Sierraville, town lots are staked off by a number of persons, and there is over 200 tons of freight at Truckee for the camp. The new company show that they have the utmost confidence in their ability to work the ores. Several tons of the ore have recently been shipped to San Francisco for trial by still another new process. If they can only work the ore "there's millions in it."

**YOUNG AMERICA COMPANY MEETING.**—At the last regular meeting of the Young America Mining Co., the following named gentlemen were elected directors for the ensuing term: A. C. Busch, Watt Hughes, Oliver Saunderson, John Saunderson and Phillip Deidesheimer. Mr. Busch was elected president and treasurer and Henry Knuthson secretary. A dividend of four cents per share was declared, aggregating \$20,000. The last cleanup amounted to \$28,700—\$200 more than was stated last week.

**THE OLIO.**—The Olio quartz mine, located between Deer Lake and Gold valley, about eight miles from town, is owned principally by T. Berger, formerly superintendent of the Marguerite mine. One hundred and fifty feet of tunnel has been run to tap the ledge, and it is expected to reach the lode in about 25 feet further. Progress has been slow on account of the hardness of the rock through which the tunnel has been run, but it is thought that a change for the better will be developed soon. Some of the quartz has been assayed by A. Maltman, the results being \$13.35 in gold to the ton and \$1.50 in silver.

**WARNER'S MINE.**—Mr. Stoddard, of Grass Valley, and C. B. Shattuck, of San Francisco, had a consultation with Harry Warner last evening in regard to the latter's mine. Through a failure to come to terms satisfactory to all parties concerned, nothing definite was arrived at. We understand that Mr. Warner wanted to pay him a certain amount of money within so many days, and that they wanted a longer time in which to raise the coin.

## Siskiyou.

**THE KLAMATH RIVER MINES.**—Yreka Union, Aug. 12: The Kanaka Co. struck good gravel on Tuesday and took out \$140. This is the first pay the company has realized, having been engaged in getting their mine in good working order. At the Fort Jones claim it was expected that bedrock would be reached yesterday, in which case the owners will soon be realizing a profit from their labors. The Phil Mott claim bids fair to pay handsomely this season. Bedrock has been reached and a large force of men are working night and day. Nothing definite can be learned as to what the Chinese companies on the river are doing, but they are pegging away and no doubt realizing big pay.

**SCOTT BAR ITEMS.**—Yreka Union, Aug. 12: The future prospects of Scott Bar seem rather bright. The company which bought Quartz Hill intends putting up a mill, which is already on the road from below. Several new locations have been made in

and near this vicinity. There is talk of the San Jose Ditch & Mining Co. starting up operations on a large scale. Brunt & Co.'s claim is paying well on French Bar. They are making good wages.

## Trinity.

**DEADWOOD.**—Cor. Trinity Journal, Aug. 12: All the mines flourish as usual. The addition of five stamps on the Brown Bear is quite an improvement and looks more like business than ever. Geo. Chenoweth, after doing a large amount of work on the Black Bear, has at last struck a lode which gives evidence of being a bonanza. The ledge is from six inches to two feet in width and prospects like old times. George is one of those faithful boys that never give up, and we hope his efforts may be crowned with success. Lamb & Co. are crushing ore from a rich and promising vein, and George Klein's cannon-ball mill is rattling away on good ore. Collopy & Kearney have purchased a half interest in a very rich vein on Thorn Gulch. Active work is now being done and the ore coming out is immense. Gibson & Leavitt on the Little Gem have a good-sized rich ledge, and are extracting ore at a lively rate. Rumor has it that Wm. Blagrove and others have struck a very rich ledge on the Brown Bear location. The vein is reported to be large and well-defined, carrying gold in paying quantities. McDonald & Franck's new tunnel is making rapid progress under the management of that scientific miner, Dick Roberts. Dave Mendenhall's dump pile is bargained for; arrangements have been made, and the dump will soon have a complete overhauling. All the mines seem to prosper, and Deadwood keeps well up to the old-time standard.

## NEVADA.

## Washoe District.

**CHOLLAR.**—Enterprise, Aug. 14: The crosscut west on the 3200 level has been discontinued and the main south lateral drift is again being advanced. Its face is in about 90 feet from the Combination shaft station and running in favorable material along the east side of the ore vein. The diamond drill is being sent east through the vein on the 3700 level from the main south lateral drift, about midway of the mine, to explore the richness of things in that direction.

**CON. CALIFORNIA AND VIRGINIA.**—The daily yield of ore is about the same—400 tons—but the quality has considerably improved the last two or three weeks, the average ore, per mill battery samples, running as high as \$16 per ton. The exploration and development work on the 1400 and 1650 levels progresses well, and a station is being opened from the old Consolidated Virginia shaft, for westward explorations at that eligible point.

**SAVAGE.**—The ore body developed by the main south or southwest lateral drift on the 600 level continues looking finely, with improvement as further developed. The best portion of the vein is a reminder of the rich ore of bonanza days. Both crosscuts west show fine ore, and it continues being hoisted to the surface through the Gould and Curry shaft.

**BEST AND BELCHER.**—On the 600 level the west crosscut has been extended 39 feet, and the east crosscut about the same distance, both in vein porphyry and clay, with small quartz s'ms. The practical building of the heavy stone bulkhead on the 2500 level, north of the Osbiston shaft, was commenced on Monday last.

**SIERRA NEVADA.**—On the 500 level north lateral drift No. 2 has been extended 48 feet, making a total of 475 feet. Material in face, vein porphyry with a little clay. A small force of men are at work prospecting the croppings on Cedar Hill, and taking out some pretty good ore occasionally.

**HALE AND NORCROSS.**—On the 3200 level good working progress is being made in the several crosscuts, east and west, with no new features of interest to report, although strongly mineralized quartz is met with, and the indications for finding the ore vein, especially to the westward, continue first-rate.

**YELLOW JACKET.**—The regular daily yield has fallen to about 100 tons by reason of 50 miners having to be drafted on account of the low stage of water in the Carson river not giving sufficient motive power to run the Brunswick mill. Steam will probably be substituted before long.

**MEXICAN AND UNION.**—Running the north west drift on the 700 level of Union Consolidated and crosscut No. 2 on the 700 of Mexican is the principal work being done in these two mines. Material in both, vein porphyry, with streaks of clay and decomposed quartz.

**OPHIR.**—The exploration work on the 1300 and 1450 levels makes the usual good progress, a southwest drift having been commenced at a point in the main south drift 340 feet south of the shaft. The repairs to the timbering of the shaft are completed.

**GOULD AND CURRY.**—North lateral drift No. 1, 150 feet above the 600 level, has been extended 39 feet, and the northeast drift from the east side of the incline station has been extended 30 feet. The material in both drifts is simply clay and porphyry.

**CROWN POINT AND BELCHER.**—The repairs to the incline engine are being pushed forward to completion as speedily as possible, but it will take another week at least.

**KENTUCK.**—Forty tons per day continues to be the regular daily yield from the old upper levels. It is simply low-grade ore which pays for milling.

**ALTA.**—The main lateral drift south from the west drift, skirting along the east side of the Keystone vein, on the 700 level, is now 183 feet in length.

## Central District.

**CONCENTRATING BY WIND.**—Silver State, Aug. 14: M. S. Thompson, who is engaged in mining at Central district, has built a small concentrator, which he runs by hand, and which separates sulphurets from quartz and gangue by a current of air forced through the machine by a blower. Mr. Thompson says the machine does good work, and he thinks can be arranged to save chlorides as well as sulphurets.

**CONTRACT LET.**—Richard Carter & Co. have the contract for sinking a new shaft on the St. John's ledge, Alta Hill. The shaft is to be 30 feet deep, under the contract, and the contractor to furnish all necessary supplies. Work was commenced yesterday.

**Columbus District.**

**HOLMES.**—Candelaria True Fissure, Aug. 14: In the east end of the seventh level we are extracting ore from the old Belle footwall ledge. The ledge has improved in size since last week. The stope below the General Thomas and near the old seventh is producing well. This stope is fully 100 feet long. The ledge is wider and the grade of the ore is better than at last report. The drift from eighth level running south to cut this ore body has not reached the ledge. The hanging wall of this ledge is very hard and progress is slower than we expected. The stope below eastern end of Bob Morris looks well and is producing good ore. We are now satisfied that this ledge is the same as the Morris, and the waste rock in the face of Morris that we supposed was the east end of Morris ledge is only a bunch of waste in the ledge. The stope below east end of eighth level is looking well and producing well. In the main tenth we are running south to cut the Yankee ledge. We are very near it and expect to cut it during the next two or three days. The General Thomas or 11th level going east is in a splendid formation and looks like we ought to cut the ledge very soon.

**MOUNT DIABLO.**—The winze from the west drift on the seventh level is down 103 feet and the south crosscut from this drift is in 41 feet. The south crosscut from the west drift on the sixth level is in 125 feet and the north crosscut from this drift is in 340 feet. We have sunk a few feet on a small streak of ore between the fifth and sixth, but at present there is very little showing. The raise from the intermediate between the fourth and fifth levels is up 12 feet and shows a small streak of ore. The drift in the intermediate between the first and second levels is in 28 feet and the face shows a foot of \$150 ore. The ore at the mill is all worked up and the cleanup will be finished in a few days.

**Eureka District.**

**ORE SHIPMENTS.**—*Sentinel*, Aug. 14: During the past week, ore shipments were made from the mines of the district to the two reduction works in town as follows: To the Richmond works—Antonazzi mine, 2 tons; Whippoorwill, 15; Endeavor, 5; Silver Lick, 27; Marguerita, 22; King Lear, 3½; White Pine, 3; Bullwhacker, 2; Excelsior, 7½; Laird, 7; Silver Connor, 45. To the Eureka Con. works—Frazier & Molino mine, 3½ tons; Paul, 1; Dunderberg, 81; Featherstone, 8½; Queen, ¼; Jackson, 25; Baldy, 2½; Alturas, 8½.

**Grantsville District.**

**RUNNING STEADILY.**—*Belmont Courier*, Aug. 14: Deputy District Attorney John Reynolds, who returned from Grantsville on Monday's Austin stage, informs us that the Alexander mill is running steadily and doing good work. The Golden Gate Concentrator, which has just been put in place by George W. Waitt, of 21 and 23 Fremont street, San Francisco, Cal., does all that has been claimed for it in a highly satisfactory manner, and John Phillips thinks that it is fully capable of concentrating the ore from 20 stamps. This ore is coming from the sixth level of the Alexander. There is an abundance of it in the mine, and if the concentrations are successfully treated, Grantsville has a good chance of becoming a live camp again and a steady bullion-producer. At present the heavy discount on silver eats up the profits that ought to go to Phillips & Kuchel, but it is hoped that silver will soon be on the up-grade. The mill is being run under the direction of C. J. Kuchel, and the mine by John Phillips, who is a miner of large experience both in California and Nevada.

**Hawthorne District.**

**LAPANTA BULLION YIELD.**—*Virginia Enterprise*, Aug. 11: The 40 tons of ore recently mentioned in this paper as being worked at the Thompson mill, Lower Gold Hill, yielded \$5100, or \$127.50 per ton. This is what might be called pretty good ore, and as for the bullion, there is no discount on that, it being nearly pure gold. There is plenty more of that rich ore in the golden Lapanta.

**Ione District.**

**ORE.**—*Belmont Courier*, Aug. 14: The chloridizers of Ione are taking out some fine ore.

**Morey District.**

**CHLORIDERS.**—*Belmont Courier*, Aug. 14: Some very fine ore is being extracted from some of the Morey mines by chloriders.

**Ophir Canyon District.**

**CHICAGO M. & M. Co.**—*Eureka Sentinel*, Aug. 10: The town of Ophir, where is located the property of the Chicago Mill and Mining Company, has a population of 150, ten of whom are women. The company named have there a mill of 20 stamps which crushes 25 tons a day. They use a White furnace, for which much excellence is claimed. The stamps never hang up unless there is a breakage or for a cleanup. The ore supply is unfailing, and if the mill were double the capacity it could easily be kept going. It has been the custom not to sort the ore closely but to run it through about as it came from the mine. By this means much that was low grade was crushed and occupied the attention of the stamps as long as 200-ounce ore would. This will now be changed and by judicious sorting the yield of the mill can be easily increased 25 per cent. It is now producing a bar of bullion a day, which runs about 4 fine in gold. H. H. Warne, who is well known in Eureka, and others have a gold mine perched on the hillside opposite the town, and are said to have very excellent prospects. They are erecting a three-stamp mill, to be run by water power to test it, and they hope it will prove a bonanza.

**THE MILL.**—*Belmont Courier*, Aug. 14: The three-stamp mill owned by Leonard, Cruickshanks & Warne is completed and will soon drop stamps on ore from their gold mine in Ophir canyon. There are quite a number of gold mines in Nye county, but for some reason or other they are not worked. They will all pay if properly handled.

**Tuscarora District.**

**NORTH BELLE ISLE.**—*Times-Review*, Aug. 12: The work on the 150-foot level has advanced 8 feet during the past week.

**NAVAJO.**—During the past week the south drift on the east vein, 250-foot level, has been extended 18 feet. The stopes are yielding the usual amount of ore.

**Wild Rose District.**

**CONCENTRATED ORE.**—*Silver State*, Aug. 16: One of the Paradise Valley Co.'s teams arrived yesterday from the mill with 24,000 pounds of concentrated ore.

**ARIZONA.**

**CHERRY CREEK.**—*Prescott Courier*, August 14: The steam arastra in Cherry creek district is doing good work; gold rock now being crushed by it is paying right well. The mill and concentrators on Groom creek are being run night and day. A lot of gold rock which Chris Linde had put through paid \$25 per ton in free gold. Mr. Craigue's tailings, from the Buzzard mine, yielded well. Mill is now crushing Parker gold rock. Col. Bigelow says he is prepared to furnish a smelter with any number of tons of good ore from his mines in Hassayampa district. We know many more mine-owners who can do quite as well. So everybody is praying for the railroad and smelter. The man who discovered the rich ledge of gold-bearing quartz near Lynx creek is very reticent concerning the same, but it is a fact that the rock is very rich.

**BRITISH COLUMBIA.**

**THE BOOM BURSTED.**—*Victoria Colonist*, August 7: A gentleman who arrived yesterday from Granite creek confirms the late reports we have given of the flat times prevailing there, and says that with the exception of Granite creek proper, and the Beaver and San Francisco claims, in the Tulameen river, all claims have been left. Along the creek extending some four miles above and below Granite City, miners are busily working, and with these it is thought that the results will be good enough; although with the exception of what was taken out last year nothing is known of the richness of the creek. Until more favorable reports of the diggings are received it is thought that more men will go in, the number of arrivals having most materially lessened.

**COLORADO.**

**THE LATEST STRIKE.**—*La Plata Miner*, Aug. 12: The latest strike in the Lake lode at Red Mountain is by far the most substantial yet made in the mine. The shaft for some weeks has been in a large body of ore, but, unfortunately for all concerned, much too low a grade to ship. Notwithstanding this drawback, the Messrs. Rapp & Co. have kept diligently at work on the shaft and Thursday morning were rewarded with the appearance of a body of ore altogether different from that previously obtained. A sample of 25 pounds was quickly made up and taken to the assay office at Ironton, and the returns brought down by Mr. David Lowenstein were 400 ounces silver and 2 ounces gold per ton. The strike was made in the level which is being run to cut the shaft, and the ore body promises to be both permanent and remunerative. The Erickson Bros. are making old Anvil mountain boom with the blasts in the Emerald mine. The boys have lately taken a lease of the property and have made a new opening on the vein. Joe brought down a fine chunk of gray copper which had been taken from the floor of the drift, and he says there is lots of the same kind left. About two tons of good-grade ore is on the dump, and a shipment will be made in a few days. Otto Mears and Ed. Hull have a lease and bond on the Tornado mine, on Lookout mountain. This mine has in early days produced some very rich gold and silver ore, but owing to various complications the works have lain idle for several years and the workings allowed to cave in. The lessees do not intend to fix up the caved portion, but have started a 250-foot crosscut, now in 125 feet. The Tornado presents a mine of rich promise, and in the hands of such energetic men as Messrs. Mears and Hull, only success can be predicted for their enterprise.

**DAKOTA.**

**TIN.**—*Custer Chronicle*, Aug. 7: Daily developments continue to more fully confirm Custer's claim to being the great tin center of the Black Hills. For seven miles in every direction she is surrounded by a continuous chain of tin locations in all stages of development, many of which give ample promise of becoming in the near future the greatest tin producers of the world. After a careful study of the subject, we do not hesitate to say that nowhere in the world have there been lodes discovered of such surprising magnitude and of such remarkable high grade.

**IDAHO.**

**THE BONANZAS OF MILO GULCH.**—*Coeur d'Alene Record*, Aug. 7: The reporter paid another visit to Wardner a few days ago, and of course went up to see the lead and galena elephants. The main tunnel of the Sullivan has been driven 260 feet, and an enormous amount of ore is in sight. The walls fairly glitter in the dim candle light. The middle tunnel of the Bunker Hill is in about 100 feet, and the visitor, even if he is not a miner, can readily perceive that there are many thousands of tons of ore in sight. Verily the tunnels show much, but the half has not been told, and it is reasonable to believe that the hundredth part has not yet been revealed. The mines could hardly be more favorably located for economical management. No hoisting works are necessary, the main tunnels are high above the concentrating works, and well-built chutes carry the glittering ore almost into the crusher. The mines are so easily worked that the superintendent tells us six men can get out all the ore that the concentrator can use, and its average capacity is 52 tons per day, from which 17 tons of concentrates are obtained, or an average of one ton of concentrates to every three tons of ore. An effort is now being made by the lessees to secure a contract that will justify the erection of a hundred-ton concentrator on the Bunker Hill side of the gulch. A few yards below the concentrator is the well-appointed assay office of C. A. Wing, assayer for the owners. Sampling works have been purchased and will soon be in operation in charge of Mr. Wing, in a building adjoining the assay office. A short distance down the gulch is the office of Mr. Bryant, assayer

for Messrs. Esler & Wardner, lessees. Visitors receive very courteous attention from the mine-owners. Not a day passes that parties are not shown about the mines and works under the guidance of Supt. Ray or some one of the owners or lessees. It is a matter of common remark that every part of the machinery runs to perfection, and all the work about the premises is very quietly and efficiently done. The mines are veritable marvels, and it is well for Wardner and the entire Coeur d'Alene that they are in the hands of able and energetic business men.

**SILVER MINERS' WAGES.**—*Wood River Times*, August 11: Taking the price of silver as a basis, the wages of miners in Idaho are higher now, at \$3.50 per day, than when they were \$4 per day. At that time silver was worth \$1.12 per ounce, and only about three and a half ounces were required to pay for a day's work; now, with silver at 91 cents per ounce, nearly four ounces are required to pay for a day's work. In silver mines, wages at \$3.50 to-day are therefore higher than when they were \$4 per day.

**THE IMPERIAL GROUP.**—Messrs. Emerson and Symons, who, with their partner Nichols, have a lease on the Imperial group, in Greenhorn gulch, were in town to-day, looking after the sampling and sale of a lot of ore. Since taking hold of the property, about three months ago, they have shipped about 13 tons of ore that netted them an average of about \$90 per ton, and have made good wages. They expect to do a little better in future.

**THE QUAKER CITY.**—Probably as rich ore as was ever seen in quantity in Idaho has been extracted recently from the Quaker City mine, in Elkhorn gulch, which is owned by Professor Jenney and others. One lot assayed 1967.30 ounces per ton; another lot assayed 2450 ounces, and another 2300 ounces. This, exclusive of lead. Not over 12 tons of this class have been shipped, to be sure; but the returns are so good that a six-inch vein would make the owners independently rich. The Quaker City is being worked under a lease, and Professor Jenney informs the *Times* that the lessee is clearing over \$100 per day.

**ORE.**—*Ketchum Bulletin*, Aug. 14: The Queen of the Hills and Minnie Moore mines at Broadford ship a carload of ore per day each, regularly. The Carrie Leonard mine has shipped about \$45,000 worth of ore this season. There is more in the mine now than ever. A ten-ton lot of ore will be shipped from the Yankee Blade mine, Boulder, about the 20th instant. This ore is of an average value of \$300 per ton. The Blackhorse mine is now looking better than for months. They now have a good ore body and the mine is producing quite a quantity of ore. Regular shipments will be made from this date on during the season. Eugene Howe, Walt Gooding, Harry Vivian and John Moore have taken a lease on the Niagara mine, Warm Springs creek. They are now working the property and have a foot vein of good ore in sight. In a short time they expect to commence shipping ore. The Niagara belongs to the Ontario company. J. P. Lockman, Louis Roberts and M. Mayue have just taken a lease and bond on the Saratoga mine, Smoky, from the owners, Fred Potthar and I. L. Lewis. The bond calls for \$10,000 and runs for one year. The mine shows plenty of ore, and is located about a half a mile from the Carrie Leonard. M. Mayue will go over and put men to work immediately. The crew of men will be added to as required.

**NEW PLACER DIGGINGS.**—*Idaho Statesman*, Aug. 7: News comes from Idaho City that new and rich placer diggings have been discovered in Long valley. The accounts of their richness are most fabulous, said to equal anything discovered in the famous Boise basin. As a result a general stampede from the basin is made to Long valley. For years mining has been going on in a small way on the tributaries of the Payette and south fork of the Salmon river in that vicinity, but the returns have not been very large. The new diggings are said to be on Spring creek, a tributary of the Payette. Recently there was some excitement in regard to placer mines in Yellow Pine basin, but investigation did not warrant the excitement. Further investigation is awaited with interest in regard to the discoveries in Long valley.

**MONTANA.**

**HOME OF THE LOCATIONS.**—There are some 9 or 10 strongly marked lodes being prospected with the most encouraging results, from each and every foot, gained in development. The Hardfoot, with a tunnel of 40 feet, shows a vein 4½ feet wide. The Razorback gives returns as high as \$105, with an average of \$24. The Rover, Humming Bird, I X L, the Daisy, Atlas, Luenna, Maine and Boss all show from 2½ to 3 feet on the surface and carry free gold, increasing in yield with the depth attained. The Little Giant Co. is piling up a large lot of fine-looking ore from its vein of about five feet in width. The Chief, a new discovery, shows six feet of ore that prospects well. The Bona Fide has 2½ feet of a vein averaging \$16. The Gypsy, Vermilion, Shooting Star, Oro Fino and Lone Star, all discovered within the past month, give promise of merging into important gold-producers. Samples of ore from a number of the above-mentioned mines have been found to contain 6.2 ounces silver and 4.2 ounces gold, which is over \$90 per ton.

**THE ANACONDA.**—*Butte Inter-Mountain*, Aug. 14: Anaconda ore is still being shipped to the smelter and no furnaces have been discontinued during the past week. The alterations and improvements already begun, as chronicled in the *Inter-Mountain*, are still in active progress and we have reason to believe that in the near future the new as well as the old concentrator, and all furnaces, will again be in full blast. This information will prove particularly cheering, and increase if possible the already firm public faith in the great future of the Anaconda company, and the 5000 men, women, and children who directly and indirectly are depending upon it for a livelihood.

**AT WORK.**—*Butte Inter-Mountain*, Aug. 14: A week ago silver was 91½ on an apparently falling market, and it was painfully realized that any considerable decline from that point would result in severe losses to the Butte mining companies and probably close some of the mills. Apprehensions of the gravest possible nature filled the minds of the mining and business men, and it was feared that the situation would grow worse. Happily the alarm

has decreased, and Hope once more spreads her wings over the camp. Silver has advanced to 92, not with a sudden jump as if caused by speculative excitement, but slowly as though the advance was of a legitimate and permanent character. With the exception of the Clear Grit, in which the force was curtailed, no mines have ceased operations. All the big silver companies are working as usual, and most of the copper concerns are following suit, though some of them are treating more silver and less copper ore. The Anaconda people are actively prospecting the Wake Up Jim, Wild Bill, High Ore and Modoc. The Bluebird is rushing the completion of its mill untirred by the condition of the silver market. The Amy-Silversmith is fully maintaining its splendid production, and on good information the *Inter-Mountain* believes there is no sign of any diminution of the custom ore supply. This explains why a much better feeling prevails at the close of the week, and the indications are that a still further improvement can be chronicled at the close of next week.

**NEW MEXICO.**

**OSCURA MINES.**—*Cor. Socorro Bulletin*, Aug. 10: I send you some ore from the bottom of my Copper Bottom shaft, about 18 feet from the surface. It speaks for itself. We have some good claims north of this, on the same lead. I am of opinion that the ore will run fairly well in silver, perhaps some gold, and most undoubtedly high in copper. The lode from which it is taken is in all probability the mother of the mountains, and in places over 60 feet wide; while the formation is just full of feeders or small veins intersecting the main lode at different places along the surface. The ledge proper is traceable for over 50 miles, running from the north end of the Oscuras, through the Little Burros, San Andres and Organ ranges. Of course, the distance from railroad communication and the scarcity of wood and water where my copper group is located have prevented owners from doing much more than assessment work for the last five years; but it is the experience of all isolated mining camps to be deserted several times before the proper facilities are found for extensive operations, and this is especially so in camps which contain low-grade ore. Still, the recent gold strike in the Magdalenas is pretty good evidence that a low-grade country can and occasionally does produce a bonanza of rich ore. I am working five men, and will continue to do so for the next month, when, if the showing is as good as it is now, I have parties interested who will not hesitate to put a million dollars into the properties. There are a number of men working in the camps north of us. One of them, Mr. Dunn, visited my camp two weeks ago with fine specimens of exactly the same character of ore as I am now taking out, filled with copper glance, copper pyrites and red oxide of copper. I have never seen better indications for gold, and would not be surprised if some one struck it big in the near future.

**RICH RETURNS.**—*Percha Shaft*, Aug. 12: Sixteen of the 10 cars of ore shipped from the Comstock mine in New Mexico to Denver, last shipment, yielded a gross value of about \$80,000, two cars containing \$55,000. Product of the mine for the first 45 days is thus estimated by Messrs. Barton & Rugg. Shipments to Socorro 222 tons, \$45,000; sacked and loose on dumps 1200 tons, \$240,000; waste dump 500 tons, \$25,000, and Denver shipment, about 300 tons, \$800,000; a total of 2215 tons, worth \$390,000.

**OREGON.**

**QUARTZ AND PLACER.**—*Jacksonville Times*, Aug. 11: The mining outlook seems more favorable than for years past. M. S. Booth, of Seattle, W. T., is in Josephine county looking after chrome and quartz. Jack Layton is still at work at his gravel diggings on Farris gulch, but will soon commence cleaning up. Several parties from Forest creek have gone to the Elliott creek to mine, now that water is low enough. A considerable force is at work cleaning out the ditch, repairing flumes and getting ready for next season's run at the Sterling Co.'s mines. There is quite a quartz excitement in Ashland precinct, nearly everybody there having one or more specimens in their possession. Considerable work is being done in the quartz mines on Wagner creek. Two mills are crushing ore at a lively rate, with good prospects. More solid work in the quartz mines is now being done than at any other time during the history of Jackson county; and not without good results, either. Work continues steadily on Baume Klippel & Co.'s quartz mill, which will be in running order before many months. The machinery for it will soon arrive. It will be a first-class one. The quartz mill which has been crushing ore from the Swinden ledge in Rock Point precinct is lying idle. It now seems doubtful whether L. D. Brown will put up the new mill talked about some time since.

**UTAH.**

**PARK NOTES.**—*Record*, Aug. 14: The work of retimbering No. 2 shaft of the Ontario is nearly completed, and it is pronounced a fine job. The force at the Crescent mine has lately been increased to about 75 men, and good results are obtained. The tramway brings down about 150 tons of concentrating and shipping ore daily. Matters at the Sampson both in the tunnel and in the lower workings are looking in an improved and encouraging condition. The good work is having a telling effect. The Apex assessment has been paid up entirely; no delinquent list this time. This certainly speaks well for the faith the stockholders have in the property and its excellent management. The grading for the Morgan Hoisting Works is completed, and the sinking of the shaft will commence at once.

**ORE AND BULLION SHIPMENTS.**—During the past week the Mackintosh sampler received 354,680 pounds of Ontario ore, 164,030 pounds of Daly, and 45,320 pounds of Sampson ore. The Crescent shipped during the week 492,385 pounds of concentrates, and 116,000 pounds of first-class ore. The Daly bullion shipment from the Marsac mill was seven bars, on the 9th, containing 7309 fine ounces of silver, and on the 11th, six bars, containing 6602 fine ounces of silver. The Ontario bullion product for the week was 32 bars, containing 17,561.35 fine ounces of silver.

JAMES' PATENT ORE CAR.

This Car has two double Tread Wheels that carry it on two pieces of scantling laid side by side, two inches apart, making a track ten inches wide for the car driver to walk upon, and only requires a narrow space in the tunnels or drifts for the track. **PRICE, \$35.00.**

We have recently furnished the contractors the machinery for LA TRINIDAD (300 tons per day) and SILVER QUEEN (100 tons per day). These mines are located in Mexico and owned in London. The Process is the Wet Concentration and the plants are, without doubt, the most substantial and complete ever built.

# TATUM & BOWEN,

34 &amp; 36 FREMONT ST., Donahue Building, SAN FRANCISCO.

91 &amp; 93 FRONT ST., PORTLAND, OREGON.

## JAMES' PATENT ROCKING STAMP QUARTZ MILL.

**PRICE, \$850.00.**

CAN BE SEEN IN OPERATION AT OUR WORKS.

It is the **CHEAPEST, SIMPLEST, MOST DURABLE** and **EFFECTIVE MILL** for the Reduction and Amalgamation of Gold Ores.

NO WEAR EXCEPT ON SHOES AND DIES.

Combined weight of Boss and Shoes (1400 lbs.) is alternately imparted to EACH Shoe with any requisite degree of rapidity.

It saves a higher percentage than any other machine, and requires no skilled labor to set up and run. Weight, 3000 pounds. Capacity, 6 tons in 24 hours through No. 40 Screen. Requires 4 H. P.

## THE FRISBEE-LUCOP MILL,

## A CENTRIFUGAL ROLLER MILL

—FOR WET OR DRY—

Reduction of Ores, Quartz, Phosphate Rock, Carbon, or other Mineral Substance to any degree of fineness in a rapid and economical manner.

Any method of amalgamation may be applied. At 300 revolutions per minute will pulverize 2000 pounds of quartz per hour to 60 mesh dry, and from 3000 to 6000 pounds wet. All wearing parts easily and cheaply replaced. May be seen in operation at the New York Metallurgical Works, 104 and 106 Washington St., and Pacific Iron Works, San Francisco. Certificates as to performance of the Mills, and any information required, furnished on application.

## THE FRISBEE-LUCOP MILL CO.,

THE Sign of the Arkansaw Cough Syrup is looking you all square in the face.

Do you want a sure, safe and reliable Cough Syrup? Are you troubled with a Cough, Cold, Bronchitis or Lung Complaint? Do your Babies keep you awake all night with Hacking Coughs, Colds in the Head, etc. Do you want something reliable in the house to meet these emergencies? We answer to all: "Go to your Druggist and get a Bottle of the Arkansaw Cough Syrup, and be troubled no more." Price, 50 cents per Bottle!

For Sale by all Druggists.

Dewey & Co.'s Scientific Press  
Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

## CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

### Sporting, Cannon, Mining, Blasting and HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.  
No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street - - San Francisco, Cal.

## THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,  
Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.

JUDSON POWDER IMPROVED.

FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blast ing Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.

## Wood River Gold Mines.

(Continued from page 121.)

is pushed in a systematic, economical and miner-like manner, but in proportion to the magnificent showing it is not half worked.

About 400 tons of high-grade ore is out on the Donavan group dumps, and the vast ore body exposed in the mines would justify the erection of a 40-stamp mill and keep it running for years.

Capitalists or mining men desiring reliable information on mining matters in Wood River district could not find a better posted or more thoroughly reliable man to address than Ole Rorem, Esq., of Hailey.

While prospectors in this district ask big prices for their locations, a number of instances of offering a reasonable price, "cash up and no grumbling," has had the effect of some property changing hands.

Captain Lusk, superintendent of Queen of the Hills and the Overland system of mines at Bellevue, is interested in the Donavan group, but, owing to his arduous duties looking after the properties, he neglects these gold prospects. If he would dispose of his interest to some mining man who would join Mr. Rorem in developing them, or let some Western company that would work the claims as they merit being worked, the captain would be doing Wood River a good turn.

If any one told the writer that there was such a rich gold belt as this one, with the prospects it has, and the fine opening for capital and mining men who desire an opportunity to get hold of a number of good-paying properties cheap, I would hardly have believed an exact statement of the merits of the district. The representative of the MINING AND SCIENTIFIC PRESS assures the readers that the facts set forth in this letter can be fully substantiated by investigation, and if anything the claims of the district have been underestimated rather than embellished.

## Mining Share Market.

Stocks have shown a little more animation this week than for some weeks past, though no specially large business has been done. Reported improvements on the 1400 level of the Consolidated California and Virginia, going toward the Ophir, carried up the prices of the stocks a little; but official information gives no justification to the rise. In the middle mines good development progress is made; but the expected good ore developments have not yet been arrived at in either Chollar, Hale and Norcross or Savage. In the latter mine some very excellent ore is being raised from the 600 level, and a good-sized deposit of the same is being developed; but it can hardly be classed as a big bonanza as yet, although the bullion proceeds will be very acceptable by way of paying development expenses.

It will take another week to complete the repairs to the incline engine in the Crown Point shaft. But even if that important work were completed there would be no certainty of resuming the work of ore extraction in full in the Crown Point and Belcher mines, owing to the sudden and rather unexpected subsidence of water in the Carson river, thus not furnishing the requisite supply of water power to the mills. The Brunswick mill has therefore been obliged to hang up a portion of its stamps, necessitating the drafting of a considerable portion of the mining force in the Yellow Jacket mine.

## Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Young America (for 28 days), \$38,500; Sierra Buttes, for July, \$29,500; Martin White, August 14, \$5619; Moulton, 12, \$12,800; Lexington, 12, \$27,200; Argus, 14, \$10,265; Monitor, 14, \$15,000; Martin White, 7, \$5693; Barbers' Mill, 15, \$2000; Thalberg & Thede, 15, \$2000; Odessa Mill, 15, \$10,200; Oro Grande, 15, \$9066; Germania, 8, \$3768; Stormont, 8, \$3440; Crescent, 8, \$12,030; Queen of the Hills, 8, \$1455; Argenta, 8, \$650; Alice, 10, \$9958; Pascoe, 10, \$1850; Queen of the Hills, 11, \$5450; Germania, 12, \$9996; Alice, 13, \$14,755; Hanauer, 13, \$3230; Queen of the Hills, 14, \$5068; Hanauer, 14, \$3385; Queen of the Hills, 15, \$1285; Hanauer, 15, \$6525. The banks of Salt Lake City report the receipt for the week ending August 11th, inclusive, of \$98,587.07 in bullion and \$57,935.25 in ore, a total of \$156,522.32.

## Our Agents.

## List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in DEWEY & Co.'s Patent Office Library, 252 Market St., S. F.

FOR WEEK ENDING AUGUST 10, 1886.

- 347,022.—TWO-WHEELED VEHICLE—T. S. Bayley, Alturas, Cal.  
347,041.—THROTTLE VALVE—Hopkins & Johnson, Austin, Nev.  
347,244.—TOY AIR-GUN—P. D. Horton, S. F.  
347,007.—SLIDING GRATE FOR STOVE OVENS—M. L. Miller, Oregon City, Oregon.  
347,251.—OILER—Elijah Moat, Los Angeles, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

THROTTLE-VALVE.—Herbert Hopkins and Alfred E. Johnson, Austin, Nev. No. 347,041. Dated August 10, 1886. This invention relates to a novel construction and operation for throttle-valves. It consists of a double disk or balance puppet-valve with guiding flanges and intermediate disk, an eccentric mounted on a shaft so as to rotate between the back of one of the valve-disks and the intermediate disk and shaft, and a handle by which it is operated so as to open or close the valve.

TWO-WHEELED VEHICLE.—Thos. S. Bayley, Alturas, Modoc county. No. 347,022. Dated August 10, 1886. This improvement on "carts" consists in connection with the axle and shafts, of loops or hangers, springs clipped to the frame, and a body supported by the springs. The object is to give the body such independence of movement as to enable the rider to counteract the unpleasant jogging motion which in ordinary carts is imparted to the body as the result of the jogging motion of the horse.

## New York Metal Market.

Telegraphic advices dated August 19th give the following New York prices:

BORAX—6½¢@7¼¢.  
BAR SILVER—91½¢ per oz.  
COPPER-LAKE—\$10.25.  
IRON—No. 1, \$17@18.00; No. 2, \$15@16.00.  
LEAD—\$4.85@4.95.  
QUICKSILVER—43¢@43½¢ per lb.

The following is the latest by mail from the "New York Metal Exchange Market Report":  
COPPER—Quiet but steady; Lake offered at \$10.15 @10.30. Transferable Notices (Lake) offered at 10.20; Transferable Notices (Chili Bars) offered at 10.55.

LEAD—Nominal at \$4.72½¢@4.80¢. Transferable Notices (Domestic) issued at 4.75.

TIN—Steady, closing at \$21.75@21.85. Transferable Notices issued at 21.75¢.

SILVER—New York, 92½¢ per oz. London, 42d. MAKER'S PRICES—At tidewater. 100 ton lots of listed irons (when brand is specified) range nominally about as follows: Lehigh, Grade No. 1, \$18@18.50; No. 2, \$17.00@17.50; Grey Forge, \$15.00@16.00.

Southern, Grade No. 1, \$18.00@18.50; No. 2, \$17@17.50; Grey Forge \$15@16.  
Prices generally ruling for metals not regularly dealt in on call at the N. Y. Exchange, covering extremes of buyers' and sellers' views. All prompt delivery.—Australian Tin, \$22.00@22.10; Billiton Tin, \$22.00@22.35; Banca Tin, \$22.40@22.80; Baltimore Copper, \$9.25@9.40; Orford Copper, \$9.25@9.40; P. S. C. Copper, \$9.25@9.40; Foreign Lead, \$4.80@4.90; Foreign Spelter, \$4.80@4.85.

COMPOUND lenses, of every possible combination, mounted in two hours' notice. C. Muller, optician, 135 Montgomery street.

THE STARR MILLS, at South Vallejo, employ 90 men regularly. The mills run night and day and convert 250 tons of wheat into flour every 24 hours.

## Books on Working Ores.

BY GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. PRICE, \$3, cloth, postage free. Sold by DEWEY & Co., Publishers, 252 Market St., San Francisco, Cal.

BY C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by DEWEY & Co., S. F.

## Testing and Working Silver Ores

An illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working samples, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles Smelting, Mexican process, Chilean process, Kroehnke's process, etc. Under "Pulverizing Machines" are described the arrastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings, and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

Price, post-free, \$2.00. Sold by DEWEY & Co., Publishers, 252 Market St.

## Practical Treatise on Hydraulic Mining.

BY AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' lynch. A very practical work for gold miners and users of water. Price, \$5, post-paid. For sale by DEWEY & Co., Publishers, 252 Market St

**A Great Repository of Practical and Scientific Information.**

One of the Fullest, Freshest, and Most Valuable Hand-books of the Age. Indispensable to every practical man. Just Ready. Price, \$2.00. Free of Postage to any address in the world.

**THE Techno-Chemical Receipt Book:**

Containing several thousand Receipts covering the Latest, Most Important, and Most Useful Discoveries in Chemical Technology, and their Practical Application in the Arts and the Industries. Edited chiefly from the German of Drs. Winckler, Elsner, Heintze, Mierzinski, Jacobsen, Koller, and Heinzerling, with additions by William T. Brandt, Graduate of the Royal Agricultural College of Eldena, Prussia, and William H. Wahl, Ph. D. (Heid.), Secretary of the Franklin Institute, Philadelphia; author of "Galvanoplastic Manipulations," illustrated by 78 engravings. One volume, over 500 pages, 12mo., elegantly bound in scarlet cloth, gilt, closely printed, containing an immense amount and a great variety of matter.

Price, \$2.00, free of postage to any address in the world.

**ABSTRACT OF CONTENTS:** Adulterations, Imitations, etc. How to Detect Them; Alloys; Artificial Gems, Pearls, and Turkish Beads; Bitters, Cordials, Elixirs, Liqueurs, Rafafias, and Essences, Extracts, Tinctures, and Waters Used in their Manufacture, and the Manner of Coloring them; Blasting Compounds, Blasting Powder, Dynamite, Gun Cotton, Gunpowder, Nitro-Glycerine, Fulminates, etc.; Bleaching; Boiler Incrustations; Bone, Horn, and Ivory, to Bleach and Dye them, and make Imitations and Compositions; Bronzing and Coloring of Metals; Building Materials, Artificial Building Stone, Mortars, etc.; Cocoa and Chocolate; Celluloid, Caoutchouc, Gutta Percha, and Similar Compositions; Cements, Pastes and Putties; Chemical and Techno-Chemical Expedients, Preparations; Cleansing, Polishing, and Renovating Agents; Colored Chalks, Crayons, Pencils, and Inks for Marking Linen, etc.; Confectionery; Copying and Printing; Damascening Steel; Decoration, Ornamentation, etc.; Dentifrices and Mouth Washes; Dyeing Woolen and Cotton Goods, and Yarns, Silk, Straw Hats, Felt Hats, Kid Gloves, Horsehair, etc.; Mordants; Electro-Plating, Galvanoplastic, Gilding, Nickelizing, Silvering, Tinning, etc.; Enamels and Enameling; Feathers, Ostrich, Marabouts, etc., how to Wash, Restore and Dye; Fire-extinguishing Agents and Means of Making Tissues; Wood, etc. Incombustible; Fireworks; Food and Food Preparations; Freezing Mixtures; Fruit and other Syrups; Fuel and Heating, Heat Insulation (Non-conducting coverings); Fusible Colors used in Porcelain Painting; Glass, Composition of the various kinds of, Colors for, and Processes for Enameling, Engraving, Gilding, Silvering, Pulverizing, Filing, Bending, etc.; Glazes for Earthenware; Glass and other Signs; Glue, Manufacture of; Household and Rural Economy; Illuminating Materials; Imitations, Substitutes, etc.; Indigo, Indigotine, and Alizarine; Inks, Lithographic, Printing, and Writing; Jeweler's Foils; Lacquers and Varnishes; Leather, Tanning and Dyeing, including Furs, etc.; Liquors and Beverages: Beer, Brandy, Gin, Whisky, Wines, etc.; Lubricants for Machines, Wagons, etc.; Marine Glue; Matches; Metal Industry: Mustards; Oils and Fats, Animal, Vegetable, and Mineral; Oil Paintings; How to Cleanse, Pack, and Varnish them, and to Restore Gilt Work; Paints and Pigments. Grinding and Mixing Colors, Graining, Imitation of Marbles. Paints and Washes for Various Purposes, etc. Paper and Paper Materials, Manufacture, Staining, etc.; Glass, Sand and Emery Paper; Perfumery, Aromatic Vinegars, Cosmetics, Extracts, Hair Oils, Pomades, Powders, Washes, Fumigating Articles, etc.; Pharmaceutical preparations; Photography; Plaster of Paris Casts which can be Washed; Preserving Meat, Milk, Vegetables, Vegetable Substances, Wood, etc., and Preservatives; Sealing Wax and Wafers; Sho-Blacking, Dressings, etc.; Sizing and Dressing for Cotton, Wool, Straw, etc.; Soap, Hard and Soft Soaps, Medicated and Toilet Soaps, etc.; Soldering and Solder; Sugars, Glucose, etc.; Textile Fabrics and Tissues; Tobacco, Smoking Tobacco, Snuff, Sternuative Powders, etc.; Vinegar; Manufacture of Ordinary and Fine Table Vinegars; Washing and Scouring, Manufacture of Washing Blue, etc.; Waste and Offal, Utilization of; Water-Glass (Soluble Glass) and its Uses; Water-proofing Compounds; Wax and Wax Preparations; Wood Gilding, Polishing, Staining, etc.; Yeasts, Manufacture of Pressed Yeasts, Bakers' and Brewers' Yeast, etc.; **Addenda.** Alloys; Antiseptic and Preservative Agents; Artificial Eyes, Manufacture of; Asbestos and its Uses; Bleaching; Bookbinding, Gilding, and Ornamenting; Bronzing Gilding, Silvering, etc.; Building Materials, Celluloid, Imitations, Substitutes, etc.; Cement Work; Cleansing, Polishing, and Renovating Agents; Colors, Enamels, Cements, Glue, Varnishes, Water-proofing Substances, etc.; Copying; Explosive Agents; Glass; Horn Combs, Manufacture of; Lubricants, Blacking, etc.; Metal Industry; Miscellaneous; Oils and Fats; Paper; Straw, Bleaching and Dyeing of; Strength of Materials; Willow-Ware; Index.

A circular of 32 pages, showing the full Table of Contents of this important book, sent by mail free of postage to any one in any part of the world who will furnish his Address.

**HENRY CARBY BAIRD & CO.,**  
Industrial Publishers, Booksellers & Importers, 810 Walnut Street, Philadelphia, Pennsylvania, U. S. A.

**LUBRICATION.**

Our readers can procure of **CHARLES J. WOODBURY** Manufacturer of Oils, 123 California St., San Francisco, a fine Lard Engine Oil, unsurpassed by any other Oil for general use, and which will flow through any feeder at all temperatures. Also, Cylinder Oils, Refined Cylinder Tallow, Lubric Compound, Farm, Machine, and strictly pure Lard Oil. The Woodbury Oils are in use on the Central, Southern, and Northern Pacific Railways, and nearly every Railroad and Steamship line on the coast.

**GOLD MINES.**

**FOR SALE—QUARTZ, AND HYDRAULIC PLACERS;** extraordinary bargains; immense vein, five miles long, sixty feet wide, free milling, ten-dollar rock. Also vast area of rich placers, hundreds of feet deep, gold from top to bottom. Plenty wood and water; rare opportunity. For full particulars, address

**CHAS. F. BLACKBURN,**  
Via Birch Creek. Blackburn Mine, Idaho.

**STANDING SEAM PLAIN ROOFING!**  
**All Paint Re-ground in Pure Linseed Oil!**

**JENKINS PATENT VALVES.**

**Gate, Globe, Angle, Check and Safety.**

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrounding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

**DUNHAM, CARRIGAN & CO.,** San Francisco, Cal.

**CALIFORNIA**  
**ARTIFICIAL STONE PAVING CO.**  
(SCHILLINGER'S PATENT.)**SIDEWALKS, GARDEN WALKS, CORRIDORS, OFFICES, CARRIAGE**  
**DRIVES, STABLES and CELLAR FLOORS, KITCHENS, Etc.**

The Courts here and in the East have decided that Artificial Stone Pavements with plastic concrete and in detached blocks, are infringements on the Schillinger Patent; and also, that when the plastic material is blocked off with a trowel and cut through far enough to control the cracking caused by shrinkage, that such pavement is in law the same as if laid in detached blocks, and is an infringement of the patent. All property-owners having such pavements laid without the license of the above Company, will be prosecuted.

## HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold  
in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co.  
(Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting  
that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works,  
Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded  
to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quanti-  
ties to suit purchasers.

**BALFOUR, GUTHRIE & CO.,**

316 California St., San Francisco.

## FULTON IRON WORKS,

HINCKLEY, SPIERS & HAYES, Proprietors.

(ESTABLISHED IN 1855.)

Office, 220 Fremont St.,

San Francisco.

MANUFACTURERS OF

BABCOCK & WILCOX BOILERS.

MARINE ENGINES AND BOILERS—  
Propeller Engines, either High Pressure  
or Compound, Stern or Side-wheel En-  
gines.

MINING MACHINERY—Hoisting En-  
gines and Works, Cages, Ore Buckets,  
Ore Cars, Pumping Engines and Pumps,  
Water Buckets, Pump Columns, Air Com-  
pressors, Air Receivers, Air Pipes.

MILL MACHINERY—Batteries for  
Dry or Wet Crushing, Amalgamating  
Pans, Settlers, Furnaces, Rotors, Con-  
centrators, Ore Feeders, Rock Breakers,  
Furnaces for Reducing Ores, Water Jack-  
ets, etc.

BABCOCK AND WILCOX BOILERS.

ICE AND REFRIGERATING MA-  
CHINERY.

MISCELLANEOUS MACHINERY—  
Flour Mill Machinery, Saw Mill Engines  
and Boilers, Dredging Machinery, Pow-  
der Mill Machinery, Water Wheels.

## ENGINES AND BOILERS

OF ALL KINDS,

Either for use on Steamboats or for use on Land.

Water Pipe, Pump or Air Columns, Fish  
Tanks for Salmon Canneries  
OF EVERY DESCRIPTION.

Boiler Repairs promptly attended to and at very moderate rates.

**RANKIN, BRAYTON & CO.,**  
.....BUILDERS OF.....  
**MINING MACHINERY.**

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

### WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

### WATER JACKET SMELTING FURNACES

### THE DUNCAN CONCENTRATOR

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

### BAKER'S MINING HORSE POWER.

Possessing ALL THE REQUIREMENTS of a FIRST-CLASS HOIST, and affording means for the CONTINUOUS OPERATION of a BLOWER, WITHOUT interfering with the HOISTING APPARATUS. It is made ENTIRELY OF IRON, no piece WEIGHS OVER 300 POUNDS. At the ORDINARY SPEED of a horse, a 700-pound BUCKET OF ORE may be raised 75 feet per minute. The HOISTING-DRUM is under the COMPLETE CONTROL of the man of the shaft, and is CAPABLE OF CARRYING 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

# \$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,  
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS**  
(\$575 00), F. O. B.

**OVER 1,000 ARE NOW IN USE.** Saves from 40 to 100 per cent more than any other Concentrator Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 '874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

## Geology of a Portion of the Rio Grande Region.

Intelligible sketches of the geological structure of the less known portions of the country are of general interest and value. Special interest pertains to the territory along our southern border and adjacent Mexican regions. We give on this page a map of the Rio Grande region in Texas, and Coahuila in Mexico, prepared by E. J. Schmitz, of New York City, to illustrate a paper recently read by him before the American Institute of Mining Engineers.

Coming from San Antonio, Texas, and following the Galveston, Harrisburg & San Antonio R. R. westward, one enters soon the Cretaceous formation, which forms a belt of several hundred miles, extending westward to the boundary of Arizona and across the Rio Grande into the State of Coahuila, Mexico. The members of this formation are very numerous and in petrographical character very diverse—from a whitish or bluish, slaty, impure limestone to a hard, beautiful blue-and-red striped and a compact, heavy-bedded, yellow-gray calcareous sandstone; from yellow and brownish-yellow calcareous soapstones or marlstones to crystalline limestones full of fossils; from argillaceous to calcareous dolomitic and bituminous marls, slates and bituminous slates, shales and whitish, yellow, blue and dark sandstones. In regard to the superposition of these members and their classification in groups, it would be very difficult to give a correct opinion after a short and hasty examination, but the heavy-bedded, yellow-gray calcareous sandstones may be named with some certainty as representing the oldest of the observed Cretaceous strata, while the yellow and brownish-yellow marlstones, the crystalline limestone, the blue and red-striped silicious limestone or calcareous sandstone, and certain dolomitic and bituminous marls belong to the middle Cretaceous. The thickness of these rocks is, in the eastern part of this formation, about 2000 feet, but further west it is greater.

While the country west of San Antonio is mostly level or slightly hilly and has an elevation of from 400 to 900 feet above the sea, we reach west of Del Rio and Devil's River (stations on the G. H. & S. A. extension) the slope of the Big mountain plateau, which extends in a south-southeast direction through New Mexico, Western Texas and Mexico, the continuation of the Rocky mountains. A few knobs or

mountains are known east of Del Rio. They are of eruptive or volcanic origin, as demonstrated by the basaltic debris along their edges.

Mounting the plateau and following the railroad, which runs for about 50 miles alongside the Rio Grande, we find the elevation increasing by degrees to 3000 and 4000 feet, until we reach the highest point along the road, in Presidio county, 4800 feet above the sea. The rocks of the country have been flat or slightly in-

of the whole plateau took place in the time defined by the deposition of these sandstones and of the calcareous rocks.

From Maxon Springs westward to the next station, one can observe these sandstones in less inclined position, or even level, while they can also be seen occasionally cropping out between the stations of Marathon and Strobel. Here we enter the southern portion of the Apache mountains, which has (with the whole

## A Simple Water-hoisting Device.

At the mine of a company in New Zealand, recently described in a Government report on the gold fields of that country, they have an ingenious but simple method of hoisting from a shaft, which, though rather slow for large operations, answers well for a small mine, where water is handy. The company has an underlie-shaft, following the dip of the lode in the main level to a depth of 312 feet, and has run levels from that. The underlie-shaft is six feet by three feet six inches, having a partition for hoisting, of three feet six inches square, the other portion being used as a ladder-shaft for the men to get up and down to their work.

The quartz is hauled up this shaft in a small truck or box, capable of holding 7 cwt. of stone. This box has wheels like a truck, and it is kept in position by rails fixed in the shaft. When the box is wound up to the top of the shaft another truck is run underneath it, and the quartz in the box is emptied into this truck from a trap-door which there is at the bottom of the box. The winding in this underlie-shaft is done by a water-balance erected outside the mine. This water-balance is a tank mounted on wheels, which runs on an inclined tramway the same length as the depth of the shaft where the winding takes place. When this tank is at the top of the incline it is filled with water, and the weight of the tank, when filled, is sufficient to bring about 7 cwt. of stone in the box up the winding-shaft. When the tank arrives at the bottom of the incline there is an iron knob projecting which opens a valve in the tank, and allows the water to be discharged. The weight of the empty box in the winding-shaft is sufficient to haul up the empty tank to the top of the incline, to be again refilled with water, so as to bring up the next loaded box. The winding-rope, five-eighths inches in diameter, made of best plow steel, is carried on pulleys in the main drive to the incline-shaft, where there is brake-gear erected so as to regulate the speed of winding. One man works the brake-gear; and also, by levers attached to telegraph wire, the same man can shut off and on the water to fill the tank or water-balance when it is at the top of the incline.

A New steel steamer for Government service on the bay has been launched at the Union Iron Works.

clined all the way up to the plateau, and the first disturbance is noticed west of Maxon Springs station, where a yellow-brown, hard sandstone comes up to the surface, bearing a number of coal-seams. This sandstone resembles very much the sandstones found in the Sabinas coal-field, Coahuila, Mexico. Whether this sandstone is true Cretaceous or not, could not be ascertained either here or in the Sabinas field, since no fossils have been procured; but it may be that it is in both places older than that.

Near Maxon Springs and north of the railroad, one can observe a peculiar profile of the rocks, highly inclined sandstones and shales being covered by horizontal calcareous rocks, doubtless of Cretaceous age. This profile demonstrates that the country must have been under sea-level after the tilting of the strata mentioned. It is very probable that the elevation

plateau) a south-southeast course. Some fair samples of anthracite, reported to come from near the Rio Grande, and east of this mountain range, were shown.

The rocks of this range, which is composed of a number of distinct mountains and knobs, are principally sandstones, etc., of Triassic and Jurassic age, and crystalline and eruptive rocks. The occurrences of coal on the plateau east and west of the Apache mountains, or in those mountains, are quite numerous.

All the coal occurrences on the high plateau in Presidio and El Paso counties, Texas, and certain others east of the plateau land in Texas and Coahuila, Mexico, represent apparently two separate horizons of beds. The upper horizon belongs to the middle and upper Cretaceous, while the lower horizon is older and is characterized by the yellow-brown, hard sandstones referred to above.

## CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

## Hints for Lubricating.

[Written for the Press.]

I wonder if any reader has missed these little notes during the past two months. I have been East finding out what there is new in lubricants, and a good many current impressions which I have long suspected I have also at last "found out."

For instance, though it reflects upon my own State pride (in soul I'm a '49-er), and though it contradicts what, sympathizing with some friends who have capital invested in California oils, I have often taught, I have at last "found out" California oil.

I took East 13 samples of the dark lubricating (sic) oils of the coast and went through a thorough chemical analysis of them, separating them into their constituent parts and making tests on machines especially invented for the purpose of determining the comparative values of lubricating oils. These machines are the Ashcroft and the Thurston. The Ashcroft has been adopted by the U. S. Government, and is uniformly used at its larger depots of supply for the purpose of testing the lubricating properties of the oils offered for national purchase. The Thurston machine, invented by Prof. Thurston, of Hoboken, N. J., is an ingenious and expensive mechanism, by which, with reasonable accuracy, both the efficiency and the durability of lubricating oils are readily determined. A fine specimen of one can be seen in the shops of the Southern Pacific Railway Company at Sacramento. The Pennsylvania Railroad Company have adopted the Ashcroft, and most of my experiments were conducted at their excellent laboratory located in the headquarters of the motive power department, Altoona, Pa.

I will not unusually lengthen these notes by adding the tables of analyses of these different oil-products of the coast, but will sum up the more important of our generalizations as follows:

The crudes of the California valleys differ from those of Wyoming in that they are largely composed of bitumen and asphalt. They contain very little paraffine or greasy substance. They are much darker in color and heavier in gravity than the crudes of Pennsylvania, Ohio and West Virginia, burn with much quicker flame and make more smoke. The flash and fire-tests of the vapors arising from the distillates of these oils did not differ materially (not more than one degree Baume) from those of Eastern crudes. We could, however, procure no wicks of sufficient capillary attraction. They would be overtaken by the inflammable oil so as to produce smoke rather than flame.

The character of our California oil seems to closely resemble that of Russia. Especially was this true of some samples from Baku and Batoum which I examined; most noticeably striking in the point of cold-test in which our coast crudes are phenomenal.

CHARLES J. WOODBURY.

## Lake Tahoe.

So many reports are spread about concerning the depth of this wondrous sheet of water that but few really know which to accept. Some reports go to show that no soundings were ever obtained in the center of the lake, and others that the greatest depth is 2300 feet. The following, ascertained from John McKinney, one of the oldest residents on the lake shore, and who assisted in taking the soundings, may prove interesting to the general public:

Fifteen miles of the lake on the State line average 1400 feet. The center of the line is 1500 feet deep. Three hundred yards from the mouth of Emerald bay the water is 790 feet deep, and four miles east thereof the soundings are 1400 feet. At Rubicon rock, 300 feet from shore, the water is 850 feet deep, and four miles out, easterly, it reaches 1460. At Sugar Pine point, one-half mile south, the depth is 770 feet, and four miles out, pitching to the north, 1500 feet. Half a mile from Idlewild the depth is 780 feet, and six miles out 1525 feet. At Saxton's old mill, near Tahoe City, 772 feet of water is found one-quarter of a mile from shore, and five miles east by north 1603 feet is reached. At Observatory point, one-quarter of a mile north-east from Tahoe City, soundings are 1300 feet, and four miles east 1640. Four miles south of Hot Springs 1645 feet, the greatest depth in the lake, is found. Blue water in any portion of the lake averages 1300 feet.

The temperature of the lake water at 800 feet is found to be 42°; at 1506 feet, 39½; at the surface, in winter time, the temperature is 44, and in deep water, during the summer, 65°.

The above will doubtless attract both interest and comment, but coming from the source it does, must be entitled to consideration. The theory of Mr. McKinney as to the original formation of the lake is that it occurred in the glacial period, and not from volcanic action, and if space permitted, his opinions on the subject would be given at this time, but it is certain that the bottom of the lake is riven, as are

the surrounding mountains, into chasms and ravines, leaving plateaus that extend for miles, as do other valleys or land. Could the water be drained from the lake the bottom would be several hundred feet lower than Carson valley, which valley was undoubtedly caused by the same operation as the lake, and was itself an inland sea or fresh-water lake.

A deal of sound sense and deep study is evidenced by Mr. McKinney's theories and argument, and it would be much to the benefit of science if they could be published.—*Carson Tribune.*

## Mining Booms.

Every one who has ever engaged in or watched gulch mining knows there is a peculiar fitness in the use of the word "boom," as applied to business. He has seen the water dammed up and forming into a pond, stagnant and quiet, suddenly liberated by a hoisted gate, go booming down the gulch, tearing and caving down the banks, and washing the gold into the sluice-boxes to be gathered by the miner. So, when the word "booming" is applied to the condition of any branch of business or a mining camp, its fitness is intuitively recognized. It signifies that enterprise has been dammed up by some great financial change and loss of confidence; that energy is stored away, growing stagnant, but all the time gathering force; that when the gate of doubt and distrust is raised the great store of energy and capital is liberated, and goes out tearing down banks, giving work for all, and washing hidden gold into the sluice-boxes of trade and commerce, to be gathered up by the workers.

No man who has ever been in a good mining camp, while the entire country was enjoying a boom, will ever forget his experience. There were no idlers, and from bootblacks to bankers, every one was prosperous; every prospect was looked upon as a probable deposit of wondrous wealth of gold or silver, and the value of even the most unpromising hole was put away up in the figures; every strike was magnified, as if by some enchanter's wand, tens had been made into hundreds and hundreds into thousands; the penniless prospector becomes a millionaire, and a beggar is transformed into a prince; the corner groceryman becomes a merchant; in the gambling-houses and gilded palaces of sin, money is as plentiful as blades of grass, and nearly every morning there is "a man for breakfast;" every stage or train brings in its load of "capitalists," who catch the fever, and "take a flyer," in the lottery of mining. It is a lottery to them, whatever it may be to the experienced miner of good judgment.

Outside of mining camps in the older regions of the country, the boom is different only in kind and degree. Only on the stock boards and in the speculative grain pits can the same quality of feverish excitement be found that characterizes the mining camp.

Booms move in cycles. Colorado has seen but two. The first was in the early days, following the discovery of gold, which culminated during the flush days of 1865. The second began in 1879, when Leadville became world-famous. There have been times when particular camps have had miniature booms, but local booms only when doubt and distrust is removed from all business circles, and the dammed-up energies and capital are liberated. A peculiar thing about them is that they cannot be found. Rich discoveries of placers or ore deposits attract no attention when the times are not ripe, and the accumulation of sudden and immense fortunes make only a ripple on the surface of affairs. During the days of a boom these things become known all over the civilized world, and aid the progress of the boom.

There have lately been discoveries in Colorado, of which the general public knows nothing, which in other days would have created an immense excitement and attracted tens of thousands of prospectors, speculators and all the hangers-on of a mining boom. In 1879 the quartzite discoveries of Red Cliff would have become known all over the world. There have been strange and rich deposits of ore extracted, and some large fortunes accumulated there, and penniless prospectors have suddenly grown wealthy. All these things have been faithfully reported to the *Tribune-Republican*, yet not to exceed 200 strangers have visited the camp. It is evident that the times are not yet ripe for another boom. When they will be ripe is the interesting question.—*Denver Republican.*

TOO MANY CLAIMS.—Would it not be well for those men about here who own from ten to a thousand claims, and never do a hundred dollars' worth of work on the whole of them during a year, to turn out and work their claims a little instead of sitting about town and blowing about their wealth—in the ground? Very few men have made big raises, excepting bills, in this manner. These mine-owners, who take up numerous claims, and hold them for years, in the hope that some one will relocate and find something while working them, so that they may step in and blackmail the relocators out of a few dollars, adopt both a slow and poor way of making a fortune. This character of men retards the development and progress of any country, and the sooner they are driven off, or sent to that mysterious country from whence no traveler ever returns, the better it will be for all—even the fellow who takes the trip.—*Pioche Record.*

## Silver Creek District.

A correspondent of the *Salt Lake Tribune* writes as follows concerning new discoveries in Eastern Oregon:

Allow me to inform you and your readers concerning this new found and remarkably rich mining region, which is in the near future destined to astonish the mining world. I must say that never before in the history of mining has a region of country offering such great advantages and facilities for mining operations, with its many mineral-bearing quartz veins, rich in the precious metals, remained unexplored, and almost untouched by the hand of the prospector until recently, although in the early days of placer mining and at a time when but little was thought or known of quartz mining, the streams and gulches which headed in these mountain ranges were filled with placer miners who took no notice whatever of the veins of quartz which had for ages been freeing themselves of the gold that supplied and fed the placers which have produced their millions. Being satisfied with the golden harvest yielded them by the gravel diggings, they abandoned them for other parts, leaving the country as wild and desolated as when they entered it. A few prospectors who have since ventured this way, in search of quartz lodes, have struck bonanzas in the way of gold and silver veins which have attracted considerable attention recently on the outside, and prospectors are beginning to pour in from every direction, who are making remarkably rich discoveries on every hand. The field for prospecting extends over a large area of country, with but little of it as yet explored by the prospector. The formation is of granite, gneiss, porphyry and slate, traversed by well-defined gold and silver bearing quartz veins, which vary in width from a few inches to 30 feet, except in the slate formation, where they are much larger, the veins in places showing an outcrop several hundred feet in width, which are probably the largest outcroppings of quartz in the world. What these immense veins may contain in the way of precious metals is a matter yet to be determined. Owing to the lack of prospectors they have never been explored. On the head-waters of Silver Creek, in the Blue Mountain range which forms the dividing line between this and Grant counties, also on the headwaters of John Day's river, on the opposite side of the range, can be found numbers of attractive quartz veins, which run a few degrees east of north, and by their cropping alone at intervals they can be traced, with the assistance of a compass, for miles. Some of these mines are now being located and developed by the energetic prospectors, who are daily arriving in the new Eldorado in search of fortunes with remarkable success. These mines in places show free milling quartz, and in places smelting ores are found that assay very high in both gold and silver. One of these veins, which is known as the Bellevue, and owned by the Cabell Brothers, who were the discoverers of this magnificent property, and for whom all credit is due for the development of the mineral resources of this region, is a vein from four to six feet in width, extending for miles through rough mountains.

## The Bellevue Lode.

In gneiss and porphyry formation the Bellevue mine is developed by tunnel, showing the vein at a depth of about 100 feet from the surface, where it is 4½ feet in width, between perfect walls and carrying several of the richest characters of silver ore, which is as rich in gold as in silver. A force of hands have been put to work taking out the vein matter which is sacked for shipment as it comes from the mine, then hauled to Baker City by wagons, where the first shipment will be made by rail to Denver, Col., or Salt Lake City for treatment. The ore is very rich and will yield several hundred dollars per ton. From indications along on this vein at the surface where it has been cut at different places, there is little or no room for doubt as to it holding its own, or increasing in width for thousands of feet through the Bellevue mountain. The northern extension of this vein was discovered three miles north and on the next mountain from the Bellevue, covered over by 12 feet of debris where the vein was exposed 5½ feet in width, between porphyry and granite walls, showing specimens of lead carbonates which assay from \$300 to \$500 per ton. The extension south from the Bellevue has also been discovered, showing up very rich carbonate ore. The mountains in this vicinity abound in numerous quartz lodes that are yet to be explored. About four miles east of the Bellevue mine, and running parallel with the Bellevue lode through granite and porphyry formation, is the magnificent California mine, where you will find further evidence of the Cabell Brothers' exertions in endeavoring to prove to the world the wealth that lies buried in the bosoms of these rough-breasted mountains, for which they have been rewarded with a bonanza almost equal and similar to the Bellevue mine. About a quarter of a mile east from the California lode is the Mother lode, the two lodes dipping toward one another with a large porphyry dike running between and parallel with them. The Mother lode can be traced for miles along its bold outcrop. At places the vein shows free milling gold quartz, while at other points in the vein it changes its character from one form of ore to another.

## Gold is King.

The town of Grass Valley has an enduring foundation. It is as the house "founded on a rock," and the rock of our foundation is good gold-bearing quartz. In all our vales and on every hillside are the sure evidences of the wealth deposited beneath our feet. Deep down in mother earth the hardy miner has forced his way almost 2000 feet below daylight; he has followed the golden veins through solid rock and picked and blasted many miles of galleries; he is still going downward, and finds still richer reward for his increased labor. Locked fast in their rocky safes, these rich deposits in our eternal hills are not to be wrested away and scattered in a day; they are safe from drouth and flood, and frost and blight and insect pests; no custodian of our deposits can take the treasure-box to Canada between two days. But, unchangeable and indestructible, the precious metal beneath our feet waits to be brought forth by the intelligence and industry of man. The gold field in the midst of which Grass Valley sits is of some miles in surface area, is thickly veined with gold-bearing ledges, and the depth is unknown, but it is known that with depth the richness of the mines increases. There is no reasonable doubt that for generations, and very likely for centuries, gold will be mined in Grass Valley. When the last fish shall have been caught from the sea, the last gold may be mined from the earth.

And above this treasure-box of ours smiles a genial sky, and the earth yields many of its fairest fruits and flowers in abundance.

But the grand fact which gives assurance of enduring prosperity and prominence to the place that can produce gold is to be found in human nature. Everybody loves gold, always has and always will love it—unless the Creator should become tired of the sort of beings that now inhabit the earth, and should people it anew with an entirely different kind of man. Gold is the only thing that all mankind delight in honoring and unite in loving—even its bright sister, Silver, is slightly spoken of by some. The gold miner need never fear that the ware he gives to the world will ever cease to be in demand. Gold will always be in fashion. The miner, too, can proudly reflect upon the enduring nature of his contribution to the world's wealth. The "golden grain" of the farmer is eaten, and its mission ends. The golden metal of the miner is coined and goes ever on and on, giving pleasure, if not blessing, to him who spends it and to him who receives it. In gold coin, labor is concentrated and wealth represented in a form such that the laborer and the capitalist can conveniently preserve or exchange his gains. The gold miner is often a hero; though his deeds of heroism are not so loudly sounded as the hero who wins a battle—and yet the hero-miner found and dug the gold which the hero-warrior's king or country had to have in order to place its armies and its hero on the battlefield. Truly, gold is king, and the miner holds up his throne.—*Grass Valley Tidings.*

## Treating Diamondiferous Material.

The treatment of the blue (the diamond-bearing material in South Africa) when mined is a tolerably simple process, although a long one. It is blasted in the mines when worked to the day with dynamite, and hauled to the surface by aerial gear of two kinds. The first is the tub and sling, the former being of from 6 to 32 cubic feet capacity, and mounted on a carriage on wire ropes anchored at both ends, on the top at the surface and at the bottom in the mine. On arrival at the surface the blue is tipped into depositing boxes, and from them passed through shoots into trucks. The second method, or sling gear, is an arrangement by which a truck of from 16 to 20 cubic feet capacity is run into a sling or cage which ascends and descends on fixed guy ropes, and on reaching the surface is at once conveyed to the depositing floors. On this account it is more economical than the slinging-tub method, and causes less handling of the blue, besides enabling from 400 to 500 loads of 16 cubic feet each to be hauled every day. At the depositing or disintegrating floors the blue is distributed about two feet thick, and after long weathering, three months or more, it is mechanically broken into pieces of about four cubic inches, and left for a further period. When the natural water has evaporated fresh water is applied, and it then slacks like lime, after which a further reduction is effected by rolling and harrowing. In this pulverized condition the blue is ripe for washing. The machine used for this purpose is called a rotary washing machine, and consists of a more or less circular pan, in which a vertical shaft rotates in the center. The pan varies from 8 to 14 feet diameter, while the shaft carries 10 radiating arms, the latter being provided with a series of teeth which project downward to within about one-half inch of the pan bottom. The blue is passed into a hopper situated above the pan, and saturated with water, whence it is conveyed by shoots into wire cylindrical inclined screens. Here all the larger stones roll out, the finer mixture passing through the screen and thence into the pan, where it undergoes the ordinary process of puddling. The lighter material passes off in a state of suspension

through an opening in the pan. The mud or tailings is led away by a shoot to a settling pit, whence it is lifted by a chain and bucket elevator to a series of screens, through which the mud runs to waste, and the water is thence returned to the machine for further use. The heavier materials, which have settled in the pan, are at the close of the day's work transferred to a gravitating machine called a "pulser," where they undergo an intermediate process of cleaning, and are thence placed on the sorting table and hand-picked both wet and dry. A rotary of this description will wash about 250 loads per diem. The entire process from the time the blue leaves the mine to that on which disintegrated material is ready occupies from four to six months.

### Costs of Mining and Milling "Free" Gold Ores.

[By HAMILTON SMITH, JR.]

The gold from all the mines for which the following comparisons are made is obtained nearly altogether by the simplest methods of amalgamation and concentration. The ore coming from the mines is first passed over grizzlies (long screens formed by parallel iron bars). The larger pieces of rock which do not drop through the grizzlies are then crushed by rock-breakers into small fragments. The fine ore is then fed to the stamp-mills, which consist of batteries each having five stamp-heads dropping in a cast-iron mortar. Electro-plated sheets of copper are generally placed inside these mortars, into which quicksilver is introduced. A sufficient supply of water is constantly poured into the mortar. The finely-crushed ore and amalgam is discharged from the side of the mortar through finely-punched or slotted screens of sheet iron, and the escaping "pulp" passes down in a thin sheet through inclined sluices over sheets of copper also silver plated. The tailings flowing from the sluices are in some cases passed over rough blankets or through buddles or vanners in order to concentrate and save the heavy particles of either amalgam or pyrites. In all the reduction works which will be spoken of, by far the larger portion of gold is obtained in the mortars and on the copper plates.

The following figures have all been derived from the official reports of the several companies, and embrace operating expenses of every kind, including dead-work in the mines, general management, taxes, etc. They do not include interest on cost of working plant, nor any depreciation of capital. No specific allowance is made for wear and tear of plant. In most cases the plant has been maintained in a perfect state of efficiency, and with the Callao mine for the past two years large additions have been made in plant, which have been charged to operation.

For convenience of comparison the several yields and costs have all been reduced to the United States dollar. The given weights are in tons of 2000 English pounds.

#### California.

The Sierra Buttes and Plumas Eureka mines are situated some 35 miles by wagon road from the Central Pacific Railroad. Wood for timbers and fuel is abundant and cheap. Mining labor costs about \$2.50 per diem. Water power is used for crushing at the Sierra Buttes; at the Plumas Eureka both water and steam are used. The lodes worked are of good size, averaging a thickness of perhaps eight feet, and are reached by adit levels.

The following results were obtained for the year 1885, when a very fair amount of prospecting or dead-work appears to have been carried on in both mines.

Sierra Buttes.—Ninety-three stamps running for first six months and 60 stamps for last six months, being an average of 76½ stamps; 54,479 tons mined, yielding \$380,145, or \$6.98 per ton.

#### COST PER TON.

Mining.....\$4.06  
Milling......56  
Management and dead work.....1.21—\$5.83  
The net cash profit per ton was hence \$1.15.

Plumas Eureka.—Sixty stamps running for entire year, 56,052 tons mined, yielding \$424,791, or \$7.60 per ton.

#### COST PER TON.

Mining.....\$4.36  
Milling......61  
Management......60—\$5.57  
The net cash profit per ton was hence \$2.03.

The Sierra Buttes and Plumas Eureka mines are owned by English corporations under the same general management, and have been operated in a very judicious and economical manner; in these regards their management compares most favorably with that of other foreign mines owned in England.

#### Dakota.

The Homestake, Father De Smet and Caledonia mines are situated near the town of Deadwood, a distance of some 250 miles from the Union Pacific Railroad. A branch of the Chicago & Northwestern road has in the last two or three years been approaching Deadwood, thus diminishing the length of wagon transportation; this branch will reach the town some time during the present year. Wood for fuel and timbers is brought to the mine by means of a narrow-gauge railroad, a distance of 15 or 20 miles. Water for mill purposes is more than usually expensive. Mining labor costs from

\$2.25 to \$3 per day. The lode or deposit worked is from 15 to 70 feet or more in thickness. The ore is hoisted to the surface by steam-power. The deepest shaft has a depth of about 500 feet. Steam is used for power by the several mills.

Homestake.—There are two mills attached to this mine—one of 80 and the other of 120 stamps; these 200 stamps have been in continuous operation for about six years. The results from 1882 to 1885 have been as follows:

Period.	Costs per ton.					Yield per ton.	Profit per ton.	Tons worked.	Cash profit available for dividends.
	Mine.	Milling.	Hauling.	General.	Total.				
1882-3	2.54	1.17	.09	.23	4.03	8.60	2.57	179,074	\$459,757
1883-4	2.71	1.31	.08	.19	4.19	5.96	1.77	191,505	337,977
1884-5	2.04	1.01	.05	.15	3.25	5.73	2.48	213,190	528,668

During this period of three years no charge whatever has been made to construction or capital account, and a very considerable amount of dead-work has been done upon the Homestake property, such as shaft sinking, etc.

Father de Smet.—The mills for this mine have 100 stamps; the large 80-stamp mill was built in 1878. I have by me the reports of this company only for the years 1883 and 1885, when the results were as follows:

Period.	Tons crushed.	Gross yield.	Cash profits available for dividends.	Per ton.		
				Costs.	Yield.	Profit.
1883....	104,100	\$354,554	\$ 95,867	2.49	3.40	.91
1885....	106,855	351,697	155,597	2.12	3.57	1.45

During these years no charges were made to capital. I understand that but very little dead or exploratory work has been done in this mine during the past three or four years.

Caledonia.—This mine has been producing bullion since August 1, 1885. The president reports the following results for the period of nine months, ending April 30, 1886:

48,848 tons crushed, yielding \$224,098, or \$4.58 per ton.  
Costs—Milling.....\$.83  
Mining and general expenses 2.07—2.95 "

Net cash profit during nine months...\$1.63 per ton.

#### Venezuela.

The Guayana gold mines are situated inland from the Orinoco river about 110 miles; the cost of transportation from the river varies from four to seven cents per pound, depending upon the character of the freight and the condition of the roads. The supply of labor is nearly altogether obtained from Barbadoes and other islands of the Lesser Antilles group. Miners and ore-handlers are paid from \$2.20 to \$3.20 per diem (at Barbadoes these same negroes only receive 25 cents per diem for agricultural labor). Outside laboring workmen are paid from \$2.20 to \$2.50 per day. The cost of living at the mines is exceedingly high. The climate, although greatly improved in late years in this respect, cannot be called salubrious; hence very large wages are paid to the higher-grade officials and to skilled mechanics brought from Europe or the United States. Wood is fairly abundant in the vicinity of the mines, but owing to the high price of labor and supplies costs delivered at the mines from \$8 to \$11 for each Spanish cord of (say) 106 cubic feet or a little less, hence being about eight-tenths of an English cord of 128 cubic feet.

El Callao.—The leading mine of the Guayana group is El Callao, which at present has a maximum depth of 750 feet vertical; the thickness of the lode worked has averaged something over five feet. The amount of water pumped from the mine varies from six to ten cubic feet per minute, or (say) a maximum of 75 gallons per minute. The expenses of El Callao company have been as follows for the past five years:

1882.—Sixty stamps running; 22,405 tons reported as crushed (in every probability an over-estimate); yield, \$1,959,063, or \$87.44 per ton.

#### COSTS PER TON.

General administration at Bolivar.....\$4.82

#### AT THE MINE.

General expense, including freight on bullion.....\$ 5.79  
Mining; mine.....\$13.70  
Pumping and hoisting.....5.21—18.91  
Milling.....11.19  
Sulphuret works, etc., built 2.70  
Supplies increased.....1.03—4.63—40.52—\$45.34

1883.—Sixty stamps running; 24,000 tons mined; yield of 24,750 tons crushed, \$2,497,746, or \$100.92 per ton.

Costs per ton—Administration at Bolivar, about.....\$ 5.60  
At the mine.....33.73—\$44.33

For this year \$58,000 was paid for new mining ground, which is not included in above costs. About \$25,000 was the cost of exchange, which is included in Bolivar costs.

1884.—Sixty stamps running; 31,261 tons mined; yield of 30,936 tons crushed, \$3,295,706, or \$106.53 per ton.

#### COSTS PER TON.

Administration at Bolivar.....\$ 5.46

#### AT THE MINE.

Mining.....\$18.27  
New shaft.....2.78—\$21.05  
Milling.....7.25  
General expense.....1.41—20.71—\$35.17

During this year \$50,000 was expended for new mining machinery, etc., which is included in above costs; \$150,000 was expended on account of construction of new mill, and \$112,000 for Union and other outside properties, which is not included.

1885.—Sixty stamps running first six months, and 100 stamps last six months; 46,868 tons mined; yield of 47,223 tons crushed, \$2,116,041, or \$44.81 per ton.

#### COSTS PER TON.

Administration at Bolivar.....\$ 1.53

#### AT THE MINE.

Mining.....\$12.03  
New shaft and machinery.....2.26—\$14.29  
Milling.....4.98  
General expense.....1.11—20.38—\$21.60

During this year \$40,000 was expended for construction of new mill, etc., \$125,000 for purchase in fee of Callao property and wood lands, and \$61,000 for Union mine, neither of which items is included in above costs.

1886.—The costs at the mine for the first six months of this year have been not far from \$16 per ton, thus showing a still further diminution in expenses.

New Potosi.—The Peru lode worked by this company has a thickness of some four and a half feet, being a little narrower than El Callao vein; the mine makes but little water. The mill consists of 40 stamps now in place, built after an antiquated design. The results for the 11 months from February 1st to December 31st, 1884, were as follows: An average of 25½ stamps running; 7456 tons crushed, yielding \$158,502, or \$21.26 per ton; the total costs for this period were \$350,111, or \$46.96 per ton.

I have not at hand returns from the other Guayana mines in the Callao (or Caratal) district, sufficiently detailed to enable me to compare their results with those of El Callao. It is generally supposed that the Guayana expenses of these mines have been from \$20 to \$40 per ton, not including costs of general management.

#### Milling Results.

In the following table is given a comparison of the milling results from the stamp-mills attached to the various mines just described. The last column of the table gives the total costs at the several mines, embracing mining, milling, taxes and general management.

Mine.	Period.	Average No. of stamps.	Tons crushed in one year.	Average No. of tons milled by each stamp per month.	Costs of milling per ton in dollars.	Total costs per ton in dollars.
New Potosi.....	1884-5	25½	7,456	27	.....	\$40.06
Sierra Buttes.....	1885	794	64,408	50	\$.66	\$ 5.82
Homestake.....	1885	60	65,973	78	1.01	6.57
Father de Smet.....	1882-3	290	179,074	75	1.17	4.08
Homestake.....	1883-4	290	191,505	80	1.21	4.19
Homestake.....	1884-5	290	213,190	85	1.01	3.25
Sierra Buttes.....	1885	100	104,100	85	.....	2.12
Sierra Buttes.....	1885	100	106,855	89	.....	2.05
Sierra Buttes.....	1885	60	22,405	31	11.19	45.34
Sierra Buttes.....	1885	60	24,750	34	7.25	35.17
Sierra Buttes.....	1885	60	30,936	43	4.98	31.96
Sierra Buttes.....	1885	80	47,223	40	.....	about \$3
Sierra Buttes.....	1885	80	.....	40	.....	\$15

It must be kept in mind that the foregoing "milling" costs do not include any portion of the charges for general management at the mine or at the home office. The amount of quartz crushed per stamp depends considerably upon the character of the ore and the fineness of the mortar discharging screens. It can, in general, be safely assumed that with the best form of Californian stamp-mill now built 75 tons per month for each stamp can be crushed. With very low-grade ores, such as those at the Homestake and Father De Smet mines, these screens have rather large slots, and nearly 90 tons per month are now crushed by each stamp. The very low crushing capacity of 31 and 34 tons per month at the Callao mill in 1882 and 1883 was due to bad mortars and the general wretched condition of the mill. Since then this 60-stamp mill has been considerably improved, and its capacity is now about 3000 tons per month, or an average per stamp of 50 tons. This is about the maximum work which can be expected from a mill of old design, such as those generally built up to the present time by English makers. The new Callao mill, which has for the past year had 40 stamps and now has 60 stamps, crushes an average of about 76 tons per month for each stamp through pretty fine screens; for May, 1886, however, each stamp crushed 83 tons, which is the maximum work thus far done by this mill. In regard to costs of milling, the Sierra Buttes heads the list, with an expense of only 56 cents per ton; the very low cost of milling at the Sierra Buttes and Plumas Eureka mines results in a considerable degree from the employment of free water power. The cost of milling with steam power at the Dakota mines is now about \$1 per ton or a little less. At these mines it will be remembered that fuel is brought to Deadwood from quite a distance, which makes it expensive. The enormous cost of over \$11 for milling at El Callao in 1882 was due to the bad condition of

the mill; the new mill at that mine now has 60 stamps, and is of the most approved design. The cost of crushing by this mill will probably be about \$2.50 per ton, or perhaps a trifle less. Under existing conditions, this is probably about as low a cost for milling as can be expected in Guayana.

#### Total Costs.

With great veins of quartz, having a thickness of 15 feet and upward, when they are worked upon a large scale under fair conditions in the United States, the total costs of mining, milling, and management now vary from \$2.12 to \$3.25 per ton as shown by the last published reports of the Father De Smet and Homestake companies. In the De Smet mine, however, I understand that but little dead-work has been done in the last few years, and probably not much timbering has been used. On the other hand, with the Homestake a large amount of new work in the mine appears to have been executed, timbering is well done, and, judging from current report, the property is worked in an excellent manner. Now that the mine is in railway communication with Chicago, the costs will probably be reduced to a little less than \$3 per ton. This figure is about as low a rate as can be expected for any similar gold mine in North America when the mine and mills are kept in a proper going condition. For mines with veins from four to eight feet in thickness and favorably located for reasonably cheap power, the cost at the Sierra Buttes of (say) \$6 per ton can be assumed to be a fair figure. For the Guayana mines the present El Callao expense of \$15 or \$16 per ton is the lowest cost thus far obtained, being at the rate of about ¾ oz. of gold per ton. The astonishing decrease in costs at El Callao from \$45 a ton in 1882 to \$15 in 1886 shows what can be done by good machinery and improved methods of management even in a locality as unfavorable for economy as Venezuela. Not much further reduction in the Callao expenses can be expected under present conditions; were however, a railway to be built from the Orinoco to the Guayana mines, the costs of operating them could be very greatly reduced, and they could then be worked at a figure not very much exceeding the expense of working similar mines in the United States.

#### Corean Gold-fields.

An official report to the State Department from George C. Foulke, United States Charge d'Affaires at Seoul, Corea, offers, as a plausible explanation of the rivalry between China and Japan for the control of Corean affairs, a belief in the mineral wealth of that country. It is reported that the Chinese Consul at Wonsan has visited the gold mines in that district, and that Chinese officials and merchants are interested there. It is certain that Chinese and Japanese are crowding into Corea, that trade is increasing imports from China and Japan considerable, exports of merchandise from Corea inconsiderable; that Corea has no coinage or currency acceptable abroad, and it is believed that there is already a flow of crude precious metals out of her ports. There is but little room to doubt that the country is rich in gold. It has been mined for centuries, and the existence, in large quantities, of gold is a matter of common repute in China and Japan, but exact information is lacking. The Government guards its mines jealously, and probably intends to retain possession of them. Attempts on the part of foreigners to obtain concessions for gold mining have failed, except so far as the Chinese have obtained a slight footing. The only practical attempt made by western foreigners was by the firm of Jardine, Matheson & Co., a wealthy commercial firm doing business in China, in 1883-84. They sent a party to explore the country between Seoul and Wonsan, but nothing of importance was accomplished until a practical miner, James Graham, was sent out. He found some excellent prospects in dust and nuggets by pan-washing, and reported that with necessary facilities the mines where he had worked would prove very valuable. Upon the reception of his report the firm sought a concession from the Government, but failed, and several like attempts have met a similar fate. So far as can be ascertained, the Corean methods of working are very primitive, and but little, if any, working of quartz has been attempted. The belief is growing that the employment of modern mining methods would result in a heavy production of bullion. Under present circumstances the export of gold and silver, mainly the former, from treaty ports from 1881 to 1884, inclusive, was about \$2,000,000 in value, so far as can be ascertained, and the export from Wonsan alone for 1885 is put at \$357,000. Rich gold-fields in Corea would be a tempting lure to adventurous Americans and Europeans.

TO DETECT ACIDS IN LUBRICATING OILS.—Acid in lubricating oils can be detected as follows: By analysis in a laboratory, or by putting the samples to be tested in a clear glass bottle with a copper wire running down through the cork air-tight. Stand the whole in a sunny place and leave for two or three weeks; then if on removal verdigris or green rust is on the copper, there is an acid in the oil. This is a rough effective test for engine-room use.

## SAN FRANCISCO:

Saturday Morning, Aug. 28, 1886.

## TABLE OF CONTENTS.

EDITORIALS.—Geology of a Portion of the Rio Grande Region; A Simple Water-lifting Device, 133. Passing Events; Investments in Mining Stocks; Bonding Mines; Volcanic Eruption in Java, 136. Bullion Production; Mining Accidents; Freaks in Climate; Idaho, 137.

ILLUSTRATIONS.—Sketch Map of the Rio Grande District of Southwestern Texas and Coahuila, 133.

CORRESPONDENCE.—Hints for Lubricating, 134.

SCIENTIFIC PROGRESS.—Mars—The Snow-Capped Planet; Rolling Window Glass; Interesting Experiment with Soap Bubbles; A New Alloy of Aluminum; Effect of Pressure on Cork; Artificial and Sun Heat; Hydrogen in Place of a Vacuum for Incandescent Lamps; Improvement in Gas Illumination; Artificial Sea Atmosphere; A New Alloy, 138.

MECHANICAL PROGRESS.—The Universality of Inventions; Grindstones and Tool-grinding; Firing Under Boilers; To Keep the Temper in Working Tools; Steam as a Heat Conductor; Setting Up Line Shafting; The Loss of Power; Speed and Friction; Railroad Axles; Machine for Cutting Oval Holes, 138.

USEFUL INFORMATION.—Filling Up Cracks; Home-made Candy; A Wonderful Liquor; To Clean Chambray; To Remove Exudations from Brick Walls; Politics; Molding Car Wheels by Machinery; Cleaning Brass; Poison Oak; To Clean Lamp Chimneys, 139.

GOOD HEALTH.—Cold in the Head; Eating Before Retiring; The Mullen Plant; The Demand for Rest; Clothing and Temperature; Heat of Fever; White Teeth; Dying from Exhaustion; Scarlet Fever; Brooding, 139.

MISCELLANEOUS.—Mining Booms; Silver Creek District; Gold is King; Treating Diamondiferous Material, 134. Costs of Mining and Milling "Free" Gold Ores; Cores of Gold-fields, 135. Lixivation of Silver Ores, 139.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, Idaho, Utah, Colorado, Oregon, Washington, New Mexico, 140-41. MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 144.

## Business Announcements.

Quartz Mills—Tatum & Bowen.

## Passing Events.

Just after our last issue went to press the Governor adjourned the Legislature until Sept. 7th, stating the purpose of the recess to be to give the legislators a chance to participate in the nominating conventions of the two great political parties, and at the same time to visit their constituents and learn their wishes concerning irrigation legislation. This week the Republican State Convention is in session in Los Angeles, but no nominations are announced up to the time of going to press. Next week the Democratic State Convention will assemble in this city. So much activity in political matters always draws attention away from industrial movements for the time being.

The Mechanics' Fair opened in this city on Tuesday. From a hurried trip through the pavilion we conclude that in the matter of mining machinery and general mechanical work this year's fair will be found to be of great interest to our readers. There are some new inventions shown, and some of the standard sort which will be made more familiar to the general public by their exhibition. We expect to present, hereafter, notes of the exhibits, for the benefit of our distant readers.

## Investments in Mining Stocks.

The "honest miner" reads how cheap money is in the financial centers, how it goes begging for three or four per cent bonds, and wonders why it doesn't seek his bonanza in some far-away gulch which might double the investment in a sixmonth. The "promoter" who has stock to sell in a phenomenal mine, "sure to pay 50 per cent a year," wonders equally why he should go begging for an investor. It seems a strange paradox to both, and in some respects it is really a very strange one. In other respects it is not at all to be wondered at.

Lately, the new bonds of a certain railroad, some 6,000,000, were offered for sale, and over \$25,000,000 stood ready to take them. The public had just sunk in that one adventure more millions than the entire cost of a year's mining in the whole State of California. This loss made it once quite as useless to go to New York with a railroad as with a mining scheme. But the public recovers from a railroad loss, because it is generally only partial, while a mining investment they say is generally a total loss. The large stock capital of the Denver & Rio Grande Railroad was largely sold above par but a few years ago. Now it has sunk almost out of sight and it may be safely asserted that this one stock has sunk more money in New York, without paying back a dollar, than has been invested all told in Leadville mines, while the latter has yielded the country near one hundred millions, and more in dividends to individual stockholders than the entire capital stock of that railroad. But the loss on the railroad is forgotten, while a Little Pittsburg and Chrysolite are remembered. The shrinkage on Western Union Telegraph stock, but a short time ago, represented a loss of near \$40,000,000, and on the entire railway list a loss of hundreds of millions. Still the public buys railway and telegraph shares, and rarely touches a mining stock that pays two to three per cent a month. There is a reason for this. The public says the permanency of a given mine is dubious. The absolute quantity of ore in it cannot be measured and made visible. Estimates of what is "in sight" are generally largely exaggerated, and the best of judges are often deceived in their measuring. In flush times many a mine was certified into the hundred thousands which would not pay expenses. This is the general and radical reason of conservative investors for not taking in mining shares as they do other stocks.

And it cannot be gainsaid that mining stocks are in disrepute with the public, for another reason: When a mine is developed, equipped and paying a fairly reliable dividend of two to three per cent a month on the price asked, as some mines are, it would seem that its stock would be greedily taken on such basis, but it is not. After getting facts as to the mine itself that would lead to investment, the fact stares them in the face from the history of all the leading mines on the stock list, that the majority interest manages a mine to suit that interest, without regard to the minority, sometimes paying dividends to enhance the stock and sometimes not to depress it, re-sawing it for the profit of the principal insiders, and no reliable information can be obtained. The writer carried some stock of record for over two years in a leading California company, and in that time never got a word of information about the property. Dividends were heard of only through the papers, but a postal card notified of assessments. No semi-annual or annual report was ever received. No commercial company would think that decent treatment of a shareholder. Many instances might be given. The wonders of the great Quihotoas bonanza were heralded everywhere not long ago, and stock was way up. There was no doubt about the magnitude and richness of the ore body. No reports of bullion shipments are made, and the mystery of Ben Nevis is greater than ever to the outsiders. At all events, the mining interest with the public has got a blow from the Quihotoas stocks, for two reasons. The most astute experts and noted mining capitalists were woefully deceived in the ore body, or they have been stock-jobbing in a way that loses all confidence in mining stocks. When these great and notable movements in mining are so managed as to disquiet the stockholders of the minority interest, there is little hope for the smaller and more inconsequential mining deals with the public.

Frank and open-handed management of the mines now on the stock market is wanted to induce the outside public to invest. Mining men can get information, but outside investors must rely on the directory of the given company. Thousands are willing to risk what they call the gambling feature of mining, and rather like it, but they want to know that any good fortune struck in the mine will be honestly administered for the common benefit alike of all stockholders. It is useless to take the former risk if the latter is to be concealed for a stock-jobbing purpose.

It would seem to be the interest of the majority party in a mine to deal fairly with all. In looking over the list, the price of dividend stock reflects the management. The Calumet & Hecla keeps its market valuation above \$20,000,000, with an eight per cent annual dividend. The Ontario holds its own. The Granite Mountain goes at the rate of \$6,400,000, and \$40,000 monthly dividends. It is known that all shareholders are treated alike. Other notable cases might be mentioned.

Confidence is everything to be secured in mine management. The public will readily invest in mining stocks when assured of the same business-like reports that are furnished by commercial corporations. A well-authenticated mine, ably and honestly managed, the outside public will readily take. At present, the great mining industry has to rely on mining capitalists for its support.

## Bonding Mines.

The bonding of mines in California and the Pacific Coast has become so frequent that a review of the situation may be of interest to our mining readers, as well as intending purchasers.

The hardy prospector, who, as he judges from experience, has found a "good prospect," seldom has the means to make more than a superficial development of the same, and unless "pay ore" is reached in a few weeks, it not infrequently happens that that is the last of the "mine."

More frequently the shallow shaft, made by the prospector and his "pard," or the "open cut," shows encouraging "signs," but not enough to warrant putting up the simplest machinery for reduction.

At this point the "mining man," with more means, or backed possibly by some financial "mine-owner" at "the bay," or elsewhere, comes to the front, and after examination makes a proposition to "bond" the mine, as it is called; that is, an agreement is entered into between the parties to furnish money to make certain developments for a certain length of time, with the privilege of purchasing a part, or the whole, at any time during the bond.

The style and conditions of the bond are such that it frequently happens that a very small omission cuts off an otherwise advantageous bargain to an intending purchaser, after expending hundreds, or it may be thousands, of dollars in prospecting.

A case in point came within our own experience. A mine in California was bonded for \$3000. Work was done on it freely, with the expectation of owning it at the end of the bond. Notice was given to the owner that at a certain day, the last but one of the bond, as it happened, the price would be paid over and he wished the deed ready. All in good time the deed was ready, and the purchaser, with evident satisfaction, handed a handsomely lithographed draft on San Francisco in payment; but the owner "did not see it." The bond was for "gold coin;" and if the gold coin was forthcoming before the bond run out, the deed was ready, and he would wait until then. As it was an impossible thing to do, and as no persuasions or threats could avail, the mine and its improvements came back into the hands of the sharp owner.

Now, as the country is overrun by "quartz sharps" and a few bona fide purchasers, and as many of our old prospectors would bond their mines to an intending purchaser if they were sure they would not be swindled out of them, we have at some pains obtained from a reliable source a *pro forma* bond, which can be varied to suit circumstances, as follows:

This Agreement, made and entered into this — day of —, 18—, by and between —, of the town of —, county of — and State of —, known herein as the first party, and —, of, etc., —, known herein as the second party (or parties), Witnesseth, that the first party is the owner by proper location,

recording and the necessary work thereon in accordance with the laws of this mining district and of the United States of America, of that quartz ledge or lode known as the — (here describe the location in detail), and that the same is free from any debt, lien, or claim; and whereas the second party is desirous of developing the same with a view to purchase: Now this agreement witnesseth that the first party agrees to bond the said mine to the second party for the period of — months from this date for the sum of — dollars, gold coin of the United States, on the following conditions (here insert the conditions as to the work to be done, or other details); and it is hereby agreed that at any time during the life of this bond the second party may demand, and the first party shall make, a good and sufficient bargain and sale deed for said mine, duly signed, sealed and acknowledged, and shall be delivered on the payment of the purchase price, the other conditions of this bond having been previously complied with, free from any debt, lien, or claim thereon. It is understood that the purchase-money may be paid in gold coin, or by certified check, certificate of deposit, or draft for gold coin on any solvent bank in —; but if paid by a certified check, certificate of deposit, or draft, then the deed shall be held in escrow by —, agent for Wells, Fargo & Co. at — (or other person agreed upon), until in due course the check, certificate, or draft shall have been paid, when the deed may be delivered by —, as agent of the first party, to the second party hereto. Should the second party fail in any of the conditions of this bond, then, upon demand of the first party, the second party shall surrender quiet and peaceable possession of the mine and appurtenances, free from all liens, debts, or claims.

It is understood and agreed that the words "first party" and "second party," as used herein, shall include and bind the assigns and legal representatives of the respective parties hereto.

Witness our hands and seals, at —, the day and year first above written.

Signed in duplicate.

(SEAL.)

(SEAL.)

This should be witnessed and acknowledged before a notary public, or a justice of the peace, and recorded in the County Recorder's office. When this is done, a bond, safe and sound for the owner and equally as good for the purchaser, will make "all straight."

If the owner wishes to make himself additionally secure, a bond can be demanded from the second party, that no debts, liens, or claims shall be allowed to attach to the mine while in the hands of the second party, or a notice can be posted on the mine, in a conspicuous place, that the owner, nor mining property, will not be responsible for any debts, liens, or claims of any party other than those created by the owner. [Signed by the owner.]

There is no doubt that many available mining properties would in this way be developed to the advantage alike of both parties.

Some purchasers will only put their money into a developed mine; in that case they must "pay the price;" whereas by investing the same amount in prospecting several mines under bonds, they may realize several valuable mines—say one out of two or three—and thus the individuals, the district and the State be advantaged.

## Volcanic Eruptions in Java.

Herr Fennema, a mining engineer, at Buitenzorg, in Java, has made observations on the recent volcanic eruptions in that island, which are of interest as setting at rest a matter on which some doubt has existed. On the authority of Junghuhn, the general belief has been that in historic times all the volcanoes of Java had thrown out solid matter only, and never those streams of lava which are so characteristic of most eruptions. But a careful examination of Smeru and Lemongau during the catastrophe of April, last year, shows that this notion must be abandoned as incorrect. The former is not only the highest but also the steepest in Java. From 700 to 1400 meters the slope is about 6°, up to 2100 it is 20°, and from 2100 to 3671 meters it is more than 30°. For a considerable way from the summit the striking cone consists wholly of the detritus thrown out regularly by the almost uninterrupted activity of the crater. Up to April, 1885, the existence of torrents of lava was unknown. On the 12th and 13th of that month a stream appeared on the southeastern side, and forced the residents on the plantations lower down to fly. The stream increased for several days, until it reached a height on the mountain side of about 2100 meters from the level of the sea.

The loss of life was due to the avalanche of stones sent down the steep sides of the mountain by the stream. Similarly, at the same time, Lemongau threw out a lava stream, but there was a curious difference between this and the one issuing from Smeru—the latter andesitic in its character, while the former was basaltic.

## Bullion Production.

It seems to be the opinion, not only among many of our own people in this State but among those in other States and Territories, that the mining interests of California are on the wane. Because of the exhaustion of our placer and other shallow gold deposits, and the cessation of hydraulic mining, it is thought that our gold product has fallen off. We hear, every year, statements made in the newspapers of the mining States and Territories of the immense prospective product of the year; but we seldom hear any predictions of California's status. Nevertheless, every year, when the statistics are compiled, it is found that California still maintains her position as second of all in total bullion product and first of all in gold product. And this is the regular thing. There is very little talk about it one way or the other among our citizens. We are hard at work all the time turning out the bullion, and have little desire to "blow our own horns."

With the cessation of hydraulic mining, men turned their attention to the quartz interest of the State. New mines now prospected are old ones reopened. We are all the time developing our gold quartz interest. Moreover, the drift-mining interests of the State are increasing in importance every day. It is a matter of congratulation to the miners of this State to know that, notwithstanding the drawbacks which they have experienced, they still maintain the lead in the gold product of the United States.

The annual report of the Director of the U. S. Mint, just issued, contains the latest statistics of production of precious metals in the United States, for the calendar year 1885. It is as follows:

The production of gold is estimated at \$11,800,000, an increase of \$1,000,000 over the estimate for the calendar year 1884. The production of silver for the calendar year 1885, calculated at the coming rate in silver dollars, is estimated at \$51,600,000, against \$48,800,000 in 1884, an increase of \$2,800,000. Colorado still retains the foremost rank as the largest producer of the precious metals, California maintaining second place. The most notable changes have been in Montana and Idaho, the production of the former having increased from \$9,000,000 in 1884 to nearly \$13,500,000 in 1885, and the latter from \$3,970,000 in 1884 to \$5,300,000 in 1885. Nevada, Utah, New Mexico and Dakota still hold their own, while the production of Arizona has slightly increased.

The coinage executed during the calendar year at the coinage mints consisted of 47,544,521 pieces, of the face value of \$56,926,810. Of this amount 3,002,313 pieces, valued at \$27,773,012, consisted of gold coin, and 31,925,544 pieces, valued at \$28,962,176, of silver coin, the remainder being minor coin. The number of silver dollars coined during the calendar year 1885 was 28,697,767. In addition to the coinage, gold and silver bars of the value of \$27,490,095 were manufactured by the mint and assay offices during the year.

The total value of bullion and coin imported into the United States during the calendar year was \$41,418,129, of which \$8,322,909 consisted of bullion and \$33,095,120 of coin. Of the total imports \$23,645,311 consisted of gold and \$17,772,718 of silver. The total export of gold and silver from the United States during the same year was \$44,697,749, of which \$11,417,207 was gold and \$33,280,542 silver. While the United States lost by net exportation during the year \$15,508,084 in silver, it gained \$1,228,180 by net importation of gold.

The report contains an elaborate review of the coin circulation of the United States. The director's advance estimate of January 1, 1886, is reviewed, as well as the estimates of his predecessor, and some errors in still earlier estimates have been corrected. The deduction from the stock of gold coin of \$15,669,981 is made for bullion in the treasury July 1, 1873, heretofore included as coin, and for an error in the exports of gold coin as reported for 1874 of \$4,654,714, a total of \$20,324,695. This, with \$30,000,000 deducted in his annual fiscal report, makes a total deduction of \$50,324,695 from the estimates made by his predecessor of the stock of gold coin in the United States. The director estimates the amount of gold coin in the United States on January 1, 1886, to have been \$533,485,453, of silver dollars \$218,259,761, and of subsidiary silver \$75,034,111, or a total stock of coin of \$826,779,325. Of the stock of gold coin, the United States Treasury held, over and above outstanding gold certificates, \$75,434,379, and the national banks \$156,353,592, including treasury and clearing-house certificates. One hundred and fifteen State banks and trust companies held on November 1, 1885, \$31,255,788, which left in the hands of the people and other banks \$270,443,603.

Of the silver dollars which have been coined, the United States Treasury owns, not represented by silver certificates, \$72,538,725, and the national banks \$6,940,628. The amount owned by private individuals and other banks, including those in the treasury represented by

certificates outstanding, was \$138,780,408. Of subsidiary silver, about \$27,000,000 was in the treasury and \$47,000,000 outstanding.

The result of his inquiries leads the director to the conclusion either that the consumption of gold and silver in the industries has fallen off since 1883 or that there is less duplicating in the returns than heretofore, as between original and secondary manufacturers.

## Mining Accidents.

The following accident happened to a miner a week or so ago in the mines of the Star district: It appears, says the *Pioche Record*, that the injured man, David Reese, while preparing to load a hole, held in one of his hands a couple of giant powder caps, and in the other a box of caps and a lighted candle. As he was going to set the box of caps down, a piece of the wick from the candle, it is thought, fell on the caps held in his hand, exploding them, and the concussion then exploded the box of caps held in the other hand. There was no person with Reese at the time of the accident, but the noise occasioned by the explosion of the caps drew the attention of men working in other parts of the mine, who went to see what was the matter. On reaching the place they found Reese about four yards from his former position, he having been thrown that distance, over a windlass, by the explosion. He was unable to move and partially insensible. Both hands of the unfortunate man were almost entirely severed from his arms, only hanging by a single cord and a piece of the skin. The right arm was torn off about midway between the elbow and wrist, slanting toward the elbow. The other was a clean cut. There was not a particle of flesh remaining on his hands. A deep gash was found across the thigh of the right leg, and his face was badly burned. With both hands hanging in this way he was taken into Milford.

A frightful accident occurred on August 12th to a miner, William Rambo, in the Silverton district, Colorado, whereby he lost his life. It was occasioned by a premature blast. The scene was in the drift of the Dreadnaught, situated in Arastra basin, which Rambo and his brother Benjamin owned jointly. They had only been working a few days, having recently obtained a renewal of their lease on the McMillan mine near by. They had prepared two holes for blasts, and Ben, leaving his brother to do the loading, went out to the blacksmith shop to sharpen up the tools. When the shots went off Ben paid no particular attention, and when he looked around a few minutes later and saw Billy sitting in his usual place on the dump, he thought no more of the affair until he heard a groan from his brother, and going up saw that his head and breast were lacerated in a fearful manner. Both shots had gone off and the accident must have happened while tamping the charge, the concussion of the first shot exploding the second. He was brought to town the same evening and was buried on Monday afternoon. Mr. Rambo was well known in Silverton as a hard-working citizen.

## Freaks in Climate.

Our correspondent, C. H. Aaron, of Nogales, Arizona, sends the following interesting note concerning peculiar meteorological phenomena in his region:

Here in Nogales we have had, and are still having, abundant and daily rains, which have clothed the hills with verdure such as I have not before seen here; yet, at places not many miles from us, scarcely any has fallen. So capricious is the distribution of the rainfall in this singular country. As I write, the down-pour is almost tropical in its profusion, and two days ago we had the greatest flood I have yet seen here, though according to the stories of old residents, it was nothing to what we are liable to see.

So far, although a couple of roofs have been blown off, only one house has fallen—that of the old-time Californian, Sam. Brannan. This house was built over a cellar which was walled with poor adobes, and on these the walls of the house were raised. The torrents from three ravines met close to the house; the water entered the cellar, the walls of which turned to soft mud, and the house fell in. Fortunately, there was no one in the house at the time. Such floods as they tell about would be disastrous to that portion of the town which is situated on the flat. And now the sun is shining.

The first African city lighted by electricity was Kimberly, with 42 Brush lamps, each of 2000-candle power. The current is also utilized there for the killing of dogs, a step suggesting the execution of death sentences by the same means.

## Idaho.

The "Short Line Mineral Belt"—Silver City—Flint and Other Districts—Concentrates, Etc.

[Written for the PRESS by FRANK W. SMITH, our Traveling Representative.]

Silver City, Owyhee county, Idaho, was at one time almost as familiar to the mining public of the Pacific Coast as the Comstock. It was owing to the stock-gambling mania that prevailed during the palmy days of the Comstock bonanzas and kindred camps that Silver City lost the greater part of her mining kings and moneyed men who were then opening up many good properties in that vicinity. Like hundreds of other deserving camps, Silver City has suffered from the effects of mining cranks with a hobby, and non-mining men attempting to manage mines. Thousands of dollars were spent in hoisting works, stamp mills, and in some instances reduction works—all previous to development or investigation as to there being ore in quantity, or the actual treatment required by the ores. Many of these plants stand to-day rusty and unfit for use. They are monuments warning capital to avoid a district thus equipped and lying dormant. Investigation by mining men results in finding these monumental failures not the fault of the district, but the useless extravagance of by-gone wild-cat stock deals, or ignorant would-be mining men with more sand than sense, and less knowledge of mining than as many cattle.

## Legitimate Mining.

It is a well-known fact that mining is being reduced to a science, and every day the business principles applied have resulted in bringing mining down to a business basis. Old played-out mining camps are almost daily developing dividend-paying properties, and capital with experience seeks deserted fields to work rather than investing in "boomed" mineral belts with rich indications. Quantity, more than quality, is sought after now. Silver City can boast of a record on the stock boards that is anything but an enviable one. It is said that "all's well that ends well." The many big steals spent in great and costly hoisting works can to-day be utilized in developing mines that will pay handsomely if worked with care and economy. The reader can form an idea of the extent the leading mines were worked on their merits by the following instance: One of the leading mines, the stock of which was held far and wide, and often was quoted "way up," placed hoisting machinery and buildings on the mine worth over \$100,000. At one time during the exciting days of the Con. Virginia and California's jump into the hundreds, every dollar in the treasury of this leading mine (\$60,000) was put into a pool, and stock in the twin Comstock bonanzas was bought and held until it went—down. This is not the only instance of "mines dealing in mines." Thus, but few, if any, mines about Silver City were worked on their merits, until lately.

## Individual Mine-owners.

Nearly, if not all, of the paying mines of Silver City are owned by individuals. Very few corporations and but little outside capital, as yet, is invested in mines in and about this once-famous camp. The revival of mining interests hereabouts is slow but sure and profitable. Many great mines equipped with costly and improved machinery are being worked by a small force of men, while the machinery stands idle overhead. Individuals who have faith in the camp in many instances have secured control of the leading big properties and by economical and miner-like management have made the dormant bonanzas producers.

## The Oro Fino Group.

The Oro Fino is a well-known mine to stock gamblers of days gone by. The property is the best equipped in the district. It is located on War Eagle mountain, near the Summit. There appear to be three parallel veins crossing the Summit but a short distance apart—the Sinker, Oro Fino and Dunganon—covering the center vein in the order named from north to south. The Cleveland, Badger and Summit on the east vein, and the New York and Banner on the west vein. The most of these mines are either owned or bonded by T. Regan, of Silver City. The Oro Fino is the center of the group and is equipped with the finest hoisting machinery in the district, the shaft-house, ore bins, boiler-rooms, etc., reminding one of some of Virginia City's leading mines and costing, I am told, \$110,000. A two-compartment shaft, nearly perpendicular, is down 370 feet. A 750-foot adit tunnel from the north crosses the shaft at the 40-foot station. Three levels run north and south from the shaft below the adit tunnel, and showing some 1500 feet of development work done on the mine. The ore body is a quartz, varying in size and grade. It is a free-milling gold ore with but a small percentage of silver. Last season Regan took out \$83,000 with five men; 70 tons yielding \$800 per ton gold. Only \$10,000 in silver out of the \$83,000 was obtained. At present Mr. R. is only working a few men. A small stringer that goes from the Oro Fino southeast into the Badger is being followed and very rich rock is being taken out. The stringer is partially decomposed iron-looking quartz and prospects in many instances as high

as \$1 per pound. The ore is being sacked and will be treated in one of the neighboring mills. The ground now developing is opened through the New York tunnel. The machinery of the Oro Fino is lying idle, but is well preserved and protected by Mr. R. and is to-day as good as when put in. The Oro Fino and the adjoining properties above mentioned would be a most desirable property for a company, as all of the group could be developed through the Oro Fino, which is equipped with machinery in keeping with the necessities of the group.

## Silver City "Concentrates."

The charge for milling ore is \$9 to \$12 per ton.

The Idaho hotel, T. Regan presiding, is one of the best in the Territory.

Florida mountain mines are producing and bringing in ore to Silver City mills.

The Cunningham 20-stamp mill is running on Black Jack ore from Florida mountain.

Scales & Wagner are running on full time with their five-stamp mill and arastras.

R. H. Leonard has a model five-stamp wet process mill running night and day on custom ore.

War Eagle mountain looms up back of Silver City like Mt. Davidson does over Virginia City, Nev.

The Ruth, on War Eagle, is in 700 feet on ledge and opening new ground that will go up into the hundreds.

Denver, Colorado, capital has bought the old Cosmos 10-stamp mill at Silver City and will put in concentrating works at once.

## Flint District.

Nine miles southeast of Silver City is the camp of Flint, now reviving under the influence of capital in the hands of a thorough, experienced and practical Colorado mining man, R. B. Stanton, of Georgetown, Colorado. The parties, Nebraska people who are represented by Mr. S., are men of means and no small experience in mining. Flint was a live camp in '68. The place was then three years old and boasted of a fine plant that cost thousands of dollars and in charge of a no less distinguished laborer than James G. Fair, who I am told was amalgamator and operator of the mammoth works then in full blast. At that time the method in vogue for treatment of silver ores was more of an experimental nature than any settled or established process. The ores of the district required different treatment to the plant then run, which was a 30-stamp mill with an O'Hara furnace for roasting. A large quantity of rich ores was mined and put through a partial treatment. The ore handled averaged over 200 ounces, and had not the Comstock and other then new and booming El Dorados enticed both miners and mining men from the district, the Nebraska people to-day would not have been able to get hold of a group of mines as rich and extensive as those they are now opening. The camp decayed to almost nothing, in fact, only two towering brick smoke-stacks, a dilapidated boarding-house and the frame-work of the old stamp mill was all that indicated the former existence of a prosperous mining camp a few weeks ago when the present company started work. The formations are granite of a porphyritic nature and shale or slate, principally the former. The ore body is a white quartz, varying in width from 2 to 12 feet. The course of the veins (there are a number running parallel) are north and south, dipping to the east at an angle which varies from 20 to 45 degrees. The claims cross the west slope of a mountain high up and lie in about the position indicated by the diagram given below, the Leviathan and its northern extensions being the lowest on the sidehill. Tunnels tapping the Leviathan and the Perseverance and their extensions need only be continued a few hundred feet to tap the Rising Star, and at a greater depth. A glance shows that a tunnel tapping any mine on the lower row or vein can be used to open and work the vein or mine directly above and alongside of it. The description of the property given here is more of a historic nature than of recent development. The group of mines owned by this company consists of 11 mines, four of which are patented. Over 60 men are at work night and day cleaning out old tunnels, shafts and inclines preparatory to properly developing the properties. On some of the claims men are quarrying out and sacking ore that will run from 100 to 800 ounces. In some of the tunnels ore is being taken out and sacked. The ore extracted no doubt has been sufficient to pay the expense of development. Why a company like this one, with their experience and money, should stop to fool with small batches of ore in old tunnels, or put a force of men gophering the surface of the whole face of a claim, and quarry and sack ore at this stage of the proceedings, I cannot imagine. The sketch of development work done by the former management will give the reader an idea of the condition of and the extent of this promising group of mines. If the stockholders of this company open their mines for the future—and to do this they should develop and explore to a certain extent before extracting any ore for shipment or treatment—and be satisfied that they have an abundance of ore get-at-able before they invest in any extensive or costly experimental plants, they will have a Comstock in a short time. Few companies can boast of as good a showing of mines, as fine a location, or as high-grade and extensive deposits as this group shows. A little time, money and a systematic development will

(Concluded on page 144.)

## SCIENTIFIC PROGRESS.

## Mars—The Snow-Capped Planet.

Perhaps the most interesting celestial event of the year will be the opposition of Mars at the end of the present month. There is so much about this remarkable planet that suggests a close resemblance to the earth, and so many of its surface features and of the natural processes occurring upon it are visible with telescopic aid, that every time it comes to opposition, that is, gets into a line with the earth and the sun, the earth being in the middle, a battery of telescopes are turned upon it with eager expectation of interesting views, if not of important discoveries. At opposition, Mars appears even with small telescopic power like a full moon of a ruddy tinge. As the magnifying power is increased, one detail after another of the diversified surface of this distant world comes into view, until it hangs in the field of the telescope a real globe, marked plainly with continents, oceans, and islands, and partially covered with clouds.

The first physical features of Mars that come into view are the snow caps surrounding his poles. The southern pole is now inclined toward the earth, and a small telescope, say of three-inch aperture, will plainly show the circular, gleaming patch of snow that covers the antarctic region of the globe of Mars. The dark ring surrounding the snow field, and sometimes called Philip's Sea, is almost equally distinct, and some of the other seas, or spots that are believed to be seas, can be seen with the same telescope. With a larger telescope more details are visible, and with the largest and best all the various features of Martian geography which are represented on some of the wonderfully complete maps of Mars that have been constructed can be seen. What a surprising thing it is that men have been able to make maps and globes representing in a high degree of completeness the surface of a world never much less than 40,000,000 miles distant from the earth.

Large telescopes, during its time of opposition, show the two tiny moons of Mars, which revolve close to the planet, so rapidly that the inner one goes through all the changes from new moon to old moon in less than a day.

Another interesting thing about Mars which can now be studied is the mysterious network of so-called canals which cover a large portion of the planet's surface, particularly in the equatorial regions. The idea that they are really canals constructed by the inhabitants of the ruddy planet can hardly be entertained when it is known that they are 60 miles and more in width.

One thing seems to be pretty certain: Mars has reached a much later stage of planetary development than the earth, and if it has inhabitants they may possibly have attained a degree of civilization incomprehensible to us. At any rate, it is a wonderful world which now beams as a ruddy star in our winter midnight sky. When the Lick telescope is placed in position at Mt. Hamilton, some new and important observations will undoubtedly be made in regard to this interesting planet.

**ROLLING WINDOW GLASS.**—A proposed method for making window glass by rolling instead of blowing has been described recently in the Pittsburgh papers and commented upon at some length. Though the description of the process is not very clear, it would seem as if the intention of the inventor is to run the molten glass as it comes from the pot between two hollow reversible rolls heated by natural gas by pipes full of perforations placed on the inside of the rolls. As the rolled glass passes through the rolls it is received on the opposite side on an iron plate, also heated, from which it is passed into the annealing furnace. If it is claimed that by this process a glass of uniform thickness and polished ready for the sash can be made, we are inclined to question the claim. If the temperature of the rolls should be any less than that of the glass when it strikes it, it will chill the surface of the glass at once, and it would lose its viscosity and malleability, the properties upon which the process would depend; while were the rolls heated as high as the glass they would be of little or no value. It is also well known that glass by touching iron loses a part of its polish, and this must be restored by "skim melting" the glass, or by polishing it as plate glass is polished. In connection with the above it may be remarked that "ondoyant" is the name given to a new, wavy translucent glass, made in St. Louis, Mo. It is rolled in sheet form, and is of all cathedral colors; one side being wavy and undulating to the touch, and the reverse side approximately smooth. The sheet is about one-eighth of an inch thick, and can be cut with diamond or wheel. When held in the light the beauty of the glass is brought out in its fullness. The diffusion of the rays is admirable. It reflects and transmits the rays equally well, and can be made of almost any shade.

**INTERESTING EXPERIMENT WITH SOAP BUBBLES.**—A, who holds a large reed or pipe, blows a soap bubble say five or six inches in diameter; B, who has a smaller pipe, and is smoking a cigar, blows a bubble one-third or half as large as A's, filling it with smoke. Before the bubbles are shaken off they are pressed together until slightly flattened at the point of contact. In a second or two the smoke from the smaller will spring into the large bubble and remain.

The smaller bubble will disappear. There is no change in size of the surviving bubble. What drives the smoke into the larger bubble? How is the place through which it passes healed? And why does not the bubble increase in size? With a compound oleate of soda and glycerine you can blow bubbles two feet in diameter. Such bubbles have been kept for 48 hours under glass. The man who doesn't provide his children with a clay pipe and wash-basin full of oleate and glycerine, forthwith, fails in his duties as a father of a family.

**A NEW ALLOY OF ALUMINIUM.**—The applications of aluminium are now considerable, and M. Bourbouze, a French physicist, has added to their number by employing an alloy of the metal with tin for the internal parts of optical instruments, in place of brass. The alloy he employs consists of 10 parts of tin and 100 parts of aluminium. It is white, like aluminium, and has a density of 2.85, which is a little higher than that of pure aluminium. It is therefore comparatively light, which is an advantage for apparatus where lightness is desired. It can be soldered as easily as brass, without special means, and it is even more unalterable than aluminium to reagents. The attention of electrical instrument makers should therefore be called to it, especially for apparatus of a portable character.

**EFFECT OF PRESSURE ON CORK.**—In solid substances no appreciable change of volume results from change of pressure; even India-rubber is extremely rigid. Cork, however, appears to be a solitary exception to this law, being eminently capable of cubical compression. The cause of this anomalous and valuable property of cork is its peculiar structure, which renders it in many respects more like a gas than a solid. Cork is composed exclusively of minute closed cells, the walls of which are readily permeated by gases, but are impervious to liquids. The cells are filled with air, which, when pressure is applied, yield readily and expand again when the pressure is removed. The impermeability of the cells to liquids prevents cork from getting water-logged.

**ARTIFICIAL AND SUN HEAT.**—No explanation has been found of the familiar fact that, while both the light and the heat of the sun pass unimpeded through glass, artificial heat is intercepted by this transparent medium. It is strange that the heat of an ordinary fire should pass freely through a layer of rock-salt, when it is unable to penetrate a pane of common glass, and it is worth observing that while the hot rays of the sun pass through glass with such perfect freedom, they cannot find their way back by the same channel. The warmth once inclosed in a hothouse cannot escape by the process that allowed it to enter the building; it must first heat the glass panes in the roof, as it would any other substance, in order to get out again.

**HYDROGEN IN PLACE OF A VACUUM FOR INCANDESCENT LAMPS.**—The well-known fact that the carbon filament of a vacuum glow lamp is gradually dissipated by some electric or thermal effect of the vacuum points to the trial of lamps in which the vacuum is discarded and its place supplied by an atmosphere of hydrogen, nitrogen or other gas which cannot oxidize or burn the filament. According to *Engineering*, Messrs. Siemens Bros. have lately been making lamps filled with hydrogen, and they find that these lamps do not become sooty on the inner surface of the glass. Next to a filament which will remain incandescent in the open air, an envelope which will remain clean and not of itself destroy the filament is a desideratum.

**IMPROVEMENT IN GAS ILLUMINATION.**—An invention which, it is claimed by gas engineers, will revolutionize the present system of gas lighting has just been perfected by Dr. Auer in the chemical laboratory of the Vienna University. Briefly described, the invention may be said to consist in rendering a cotton wick incombustible by impregnating it with a metallic liquid. Thus treated the wick, instead of burning, merely glows, emitting a radiance not unlike that of the electric light. The whole process is very simple, and the great advantage of the invention is that it may be applied to any gas burner.

**ARTIFICIAL SEA ATMOSPHERE.**—As a means of producing an artificial sea atmosphere in houses, the use has been suggested of a solution of peroxide of hydrogen, containing one per cent of ozonic ether, iodine to saturation, and 2.50 per cent of sea salt. The solution, placed in a steam or hand spray diffuser, can be distributed in the finest spray in a room at the rate of two fluid ounces in a quarter of an hour. It communicates a pleasant odor and is said to be as good a purifier of a sick chamber as ever used, besides being a powerful disinfectant.

**A NEW ALLOY.**—The formula of a new alloy is given in *Nature*, which is especially adapted to many important uses in the arts. It melts at the low temperature of moderately hot water, and considerably below that at which the magic spoons of long ago melted in a cup of tea. Its composition is as follows: Bismuth, 48 parts; cadmium, 13; lead, 19; tin, 20. It is said that this alloy will withstand quite a severe pressure.

## MECHANICAL PROGRESS.

## The Universality of Inventions.

We do not often stop to think how little man has or enjoys that is not the fruit of invention. Things which man has long had we have ceased to think of as inventions, and we are apt to apply that term only to modern things—to things the origin of which we know. Yet it will be hard for any of us to name anything which we use or enjoy which is not an invention, or the subject of an invention, in its adaptation to our use.

The air we breathe and the water we drink are provided by nature. But we drink very little water except from a cup or vessel of some kind, which is a human invention. Even if we drink from the shell of a gourd, we are using a thing which, in the shape we use it, is a human contrivance; and the contrivances which man has devised for obtaining water and distributing it have been among the most wonderful and ingenious of any which have occupied the human mind. Bountifully as nature has provided water and placed it within the reach of man, yet we do in fact get or use but little of it except by the aid of inventions.

The air surrounds us at all times, and we cannot help using it if we would; but, if we want it either hotter or colder than we find it, we must resort to some invention to gratify our want. If we want it to blow upon us when it is still, we must set it in motion by some contrivance, and fans among other things have been invented for that purpose. A large amount of human ingenuity has been expended upon devices for moving air when we want it moved, upon fans, blowers and ventilators.

How small a part of our food do we take as animals do—in the form provided by nature—and how very large a share in some form contrived by man! We drink infusions of tea or coffee without thinking that the compounds are human inventions. How large a place the milk of the cow has in the food of man, but how little of it could he have but for a multitude of contrivances! We think of butter as we do of milk—that it is a production of nature; and so it is, but its separation from milk is an invention which has been followed by a host of inventions to effect the separation easier or better.

Sugar is a production of nature, but little known a few hundred years ago. Separated from the plants in which it is formed, it is an invention of man. The savage who first crushed some kernels of wheat between two stones and separated the mealy interior from the outer skin, invented flour, and the human mind has not yet ceased to be exercised on the subject of its improvement.

## Grindstones and Tool-grinding.

Though probably no workshop tool pays better for the care bestowed upon it, or affects the work of the entire shop, more than the grindstone, yet it is almost an exceptional occurrence to find a good stone, properly hung, running true and in perfect order. The shop stone generally has a trough beneath it to hold the water, and being usually left with a portion of its edge immersed, that part becomes softer than the remainder, and the stone wears unevenly. The out-of-doors grindstone soon becomes a worthless wreck from the effects of the weather, the sun's rays warping the wooden frame and making the stone itself too hard for use. Every employer of edge tools should endeavor to get a grindstone that will do its allotted work well and in the quickest time. A good grindstone, to replace one that is hard and flinty, is always a paying investment. A writer on the economic conduct of workshops recommends that a bad grindstone should be broken up, as the best means of saving time and trouble and earning the thanks of those who would otherwise have to use it.

Although the applications of a grindstone are limited, in its sphere it acts to perfection, and does that work which cannot be executed by the planer, lathe or milling machine. No machine or process has yet been devised to supersede the grindstone, and improvement has not added to, nor invention displaced, this primitive tool. True, science has produced artificial compounds which take the place of the original natural stone, and are now often used advantageously, but they are new only in the method of manufacture. Only those who have used a good stone, properly mounted, with its edge running as true as a turned wheel, can appreciate the value of a grindstone, and only such a stone can be applied to fine work. Those who have worked only at a lumpy, badly-kept stone cannot form a just estimate of the value of grindstones as applied to the production of the edges of tools in hardened steel. Artificial grindstones are made by binding together silicious particles with silicate of lime, and the process of manufacture is this: Silicate of soda, which is a kind of water-glass, is first made by dissolving flints with caustic alkali. Silicious sand of fine and even grain is then mixed with the plastic mass, and the whole is molded to the proper shape. In some cases the stone is treated chemically to render it hard; hydraulic pressure is employed to solidify the material. Some stones acquire their hardness by simple exposure to the atmosphere. According to the fineness of the grains of sand used the texture of the stone is modified, and emery may be used in

its stead, resulting in a grindstone of exceptionally good quality; and these artificial stones are in many cases cheaper than the natural stone to quarry and shape, which necessitates the expenditure of considerable time, sometimes with useless results.

**FIRING UNDER BOILERS.**—With a properly constructed combustion chamber under the boiler, and with air admission above the grate bars, the fire-door will not be required to be opened as often as with a boiler set to receive its air supply through the bars only; as in the former a thicker layer of coal can be carried and less slicing will be required, thus producing less clinker, and the air admission is not obstructed by ashes and clinker. For, as a rule, the fewer times the fire-door is opened the better; not that the introduction of the coal in large quantities is to be recommended, but because each time the furnace-door is opened there is a rush of cold air into the furnace, which tends to cool the combustion chamber and to bring on leakage of the boiler seams from the contraction arising from cooling.

**TO KEEP THE TEMPER IN WORKING TOOLS.**—It seems to me that after tools are properly hardened we ought to consider how to keep the temper in them when they are doing heavy cutting. There seems to be no effective way of getting water, or some cooling mixture, on the tools to keep the heat down. In the case of turning wrought iron, the point of the tool is buried in the metal, therefore the common custom of dropping water on the outside above the tools can do very little good. The place where the water is required is underneath the surface of the cut where the tool is acting, and the only way to get at this is to force the water in a fine jet from the under side.—*Journal of Progress.*

**STEAM AS A HEAT CONDUCTOR.**—Steam is as bad a conductor of heat as air as long as it does not condense, but in condensing steam will conduct heat to a cold surface at an almost infinite rate, for as the steam comes up to the surface it is virtually annihilated, leaving room for fresh steam to follow, which it will do, if necessary, with the velocity of sound. If, however, there is the least incondensable air in the steam, this will be left as a layer against the fresh steam. Experiments have shown that 5 or 10 per cent of air in the steam will virtually prevent condensation.
